House of Commons, and seeing that the session was wearing away, it was thought desirable not to allow the matter to sleep; and the Secretary to the Committee late in April addressed the Earl of Aberdeen, the First Lord of the Treasury, and requested an interview for the Committee with his Lordship. This was readily conceded, and, on the 12th of May, the members of the Committee waited upon Lord Aberdeen in Downing Street, and enforced upon his Lordship the necessity for immediate steps being taken. They were introduced on this occasion by Earl Beauchamp. The deputation were received very politely by his Lordship, who, after listening attentively to a statement of their principles, and also being put in possession of the draft bill, assured the deputation that he fully appreciated the importance of the Association, and the objects they had in view; and that he should be most happy to afford them every facility in his power, and, unless some unforeseen obstacle should arise, he hoped to be able to carry out their wishes. They regret, however, to state that, since that time, Lord Palmerston has declared in the House of Commons that government will not be prepared to introduce a bill for medical reform this session.

"Your Council have much gratification in thus submitting to the Association the results of these communications with Her Majesty's Government. The conviction has always been firmly impressed upon the minds of those who have entertained the question of Medical Reform, that, before it could be brought to a successful issue, it must be taken up by government, and carried by them through Parliament. The time has at length arrived when the First Minister of the Crown and Her Majesty's Principal Secretary of State have declared that they will do all in their power to settle this complicated question, and the final success of our prolonged exertions is therefore no longer doubtful; but the members of the Association must be aware that, even under the present promising aspect, they must not be supine. They should press the importance of an early settlement of the question upon their representatives in Parliament, and upon the House of Lords. Petitions should be sent to both Houses of Parliament; and, wherever a member of the profession resides, from thence a petition should issue."

It is deserving of record, showing the admirable zeal with which the Committee have been actuated, and to which, in a great measure, may be attributed the success that has hitherto attended their labours, that, although the members of the Committee reside many miles apart, in different parts of the kingdom, and many meetings have been held, yet, so punctual has been the attendance, that a sufficient number have always been present to transact the business.

"**BENEVOLENT FUND.** The Benevolent Fund has struggled on through many difficulties, continuing its unwearied course of purest charity. At present, its income cannot be told; but it is hoped that it will not be less than the preceding year. The number and the urgency of the cases relieved will, it is expected, be found to exceed that of any former year, augmented as it has been by cases sent for relief from the Medical Benevolent College. It is hoped that the difficulties of the Benevolent Fund will at once be removed by the liberal contributions of the members of the Association.

"The Council conclude with the hope that a long and prosperous career is yet in store for the Association, and that the success which has hitherto attended this excellent institution may be the means of calling forth the zealous exertions of the members, and of increasing its usefulness.

"**CHARLES HASTINGS, M.D., D.C.L., President.**"

Dr. DAY, Professor of Medicine in the University of St. Andrews, moved the adoption of the Report. He said he hoped it would not be necessary to discontinue the publication of the volume of *Transactions*.

Mr. BOWLING, of Hammersmith, seconded the motion.

Dr. TUNSTALL, of Bath, thought that it would be better simply to receive the report, and to consider along with it the Report of the Journal Committee, so that they might have the whole question of finance brought before them at one view. He might afterwards wish to move as an amendment, that those words be left out of the Council report which pledged the Association to discontinue the volume of *Transactions*.

The PRESIDENT thought there was no pledge given in the report, such as that which Dr. Tunstall dreaded.

Dr. TUNSTALL said that, if that were clearly understood he had less objection that the report should be adopted. At the same time he thought that no correct opinion could be formed as to the financial condition of the Association till they had heard the report of the Journal Committee. For that reason, the two

documents ought to be taken together; but he would not wish to divide the meeting on this question.

The motion of Dr. Day was, after some conversation, put and carried unanimously.

REPORT OF THE JOURNAL COMMITTEE.

Dr. COWAN, of Reading, read the following Report:—

"The Committee, appointed at the anniversary meeting of the Provincial Medical and Surgical Association, held at Oxford on the 21st and 22nd days of July, 1852, with power to carry out Dr. Cowan's proposition there adopted, "That the Provincial Medical and Surgical Journal be published weekly, and that it be edited and published in London", beg to present a report of their proceedings.

"The scheme of publishing the Journal in London at first met with opposition from the Central Council, on the ground of alleged informality in the proceedings of the meeting at Oxford. This opposition, however, was afterwards withdrawn by a resolution passed by the Council; and the Committee acknowledge with pleasure the readiness with which aid has been subsequently afforded to them by Sir Charles Hastings, the President of the Council, and Mr. Sheppard, the General Secretary. As the preliminary disagreements have long ago entirely ceased, it is neither necessary nor expedient to make any further allusion to them.

"The Committee originally consisted of Dr. Cowan of Reading, Dr. Forbes of London, Dr. Greenhill of Hastings, Dr. Webster of Dulwich, Dr. Edwards of Benarth, Conway, Samuel Crompton, Esq., of Manchester, and Thomas Hunt, Esq., of London. Of these, however, Mr. Crompton and Dr. Forbes declined to act. Dr. Cowan has acted as Chairman, and Mr. Hunt as Secretary to the Committee.

"Your Committee, at a meeting held on August 5th, 1852, offered to Dr. John Rose Cormack the appointment of Editor of the Journal, with a salary of £250 per annum; which offer was accepted by him. A copy of Dr. Cormack's letter of acceptance is subjoined.

"Putney, August 10th, 1852.

"DEAR SIR,—I have received your letter of the 7th instant, communicating to me a resolution of the Journal Committee of the Provincial Medical and Surgical Association, passed on the 5th, to the effect, that I "be requested to undertake the editorship of the Journal at £250 per annum, commencing from January 1853."

"In reply I beg to say, that I very highly appreciate the honour of having being selected by the Committee for so responsible an office; and that I accept it, under a deep conviction of the difficulties with which it is surrounded, but likewise with the faith that they can be satisfactorily overcome, provided that I earnestly devote myself to the work, and so secure the confidence and cooperation of the members of the Association.

"While I unconditionally accept the terms offered by the Committee, I trust that I may be permitted to say that an ultimatum of £250 per annum is not a sufficient encouragement to any one to embark in this enterprise with the needful toil and determination. It would be no burden to the Association to allow an increase in my salary, dependent upon an increased income from advertisements, the sale of the Journal, and from an increase in the number of members over the number on the roll at the Oxford meeting. I hope that there is no impropriety in my making this suggestion, as the increase in my salary would only come from funds which could be distinctly traced to the greater success of the new plan. If £250 were given for editing a fortnightly Journal, it does not seem wrong to point out the propriety of giving to the editor of the weekly paper an opportunity of getting a larger sum without taxing the Association.

"There is one other remark which I feel anxious respectfully to submit to the Committee. To carry out with vigour such a Journal as we are determined to have, diversity of talent and variety of style are required in the different departments; and were it even physically possible for an editor to write all the critical notices and scientific summaries, in addition to the strictly editorial duties, an uninviting sameness, and a want of familiarity with many topics, would be constantly appearing. An editor ought always to be able to know where to apply for sound information; but no editor, even though his qualifications far exceeded those to which I can lay claim, ought to venture to speak with authority on all the various questions which are constantly arising within the vast boundaries of medical science. It is, therefore, obvious that, as soon as circumstances permit, a certain sum of money ought to be placed

annually at the disposal of the editor for the payment of contributors. In the mean time, I have received promises of the most disinterested and generous aid, from several very able friends; but on a long continuance of unremunerated labour, the Association ought not to calculate.

"Sincerely thanking you for the confidence which you have placed in me, and trusting that I may be enabled to merit it,

"I remain, sir, yours sincerely,

"To THOMAS HUNT, Esq."

"JOHN ROSE CORMACK.

"Dr. Cormack commenced his duties in the beginning of Jan. 1853, since which time the Journal has been published weekly in London, under the title of the ASSOCIATION MEDICAL JOURNAL.

"At a meeting held on 29th September 1853, your Committee, having previously applied for and received tenders for the printing of the Journal, determined on making arrangements with Mr. Thomas Richards, of 37 Great Queen Street, Lincoln's Inn Fields, for the performance of that duty. The terms of Mr. Richards's contract included also accommodation on his premises for publication, and for the general commercial business of the Journal.

"Your Committee resolved that the Journal should generally consist of twenty-four pages, of the same size as the *Lancet*; but that it might, under certain conditions, occasionally contain thirty-two pages. During the six months ending 12th July 1853, the large sheet has been used on eight, and the small sheet on eighteen occasions. It was considered best to leave the carrying out of the arrangements entirely in the hands of the Editor.

"Your Committee also determined that a sum should be allowed for literary contributions and woodcuts, not exceeding £50 per quarter.

"As the details and working of the scheme were confided to Dr. Cormack, the report of his proceedings, as embodied in a letter from him, is subjoined.

"July 2nd, 1853.

"GENTLEMEN,—It is with much satisfaction that I lay before you a detailed account of the manner in which I have endeavoured to perform the duties entrusted by you to me, in the management of the Journal of the Provincial Medical and Surgical Association.

"In accordance with your directions, I have been regulated by the following general rules:

"1. That the size of the Journal should not exceed twenty-four pages, unless when the number of advertisements, or an available balance of money, justified the occasional use of a larger sheet consisting of thirty-two pages.

"2. That the expenses to be incurred for literary contributions and woodcuts should not exceed £50 per quarter.

"With reference to the size of the Journal, I have to report that, during the first half of this year, embracing twenty-six weeks, the large sheet has been used upon eight occasions, viz., January 7th and 21st, February 11th, March 11th, April 8th, 15th, and 29th, and May 27th. In accordance with your wishes, the following is the basis upon which the extreme limit of expenditure has been estimated. There has been considered as available for the Journal the amount of the annual subscriptions of members, except £305 per annum, the sum stated by Sir Charles Hastings to be required, or at least which might possibly be required, for other Association purposes. As this sum is probably more than will be required, it may be regarded as covering the non-payment of subscriptions by some members.

"To-day, the number of paying members on the list is 1,890, of whom 420 have entered the Association from Jan. 1st, 1853. Some days ago, when the subjoined calculations were made, the number of members on the list was 1,869; so that it must be borne in mind that the actual condition of the Association is in reality a little more favourable than appears from the figures about to be quoted.

"Assuming, then, 1,869 as the number of subscribing members, the Journal treasury for the year 1853 has been credited with £1,062:9:0, minus the £305 formerly alluded to; or, in other words, with £1,057:9:0, the half of which is £528:14:6. The gross income from advertisements during the twenty-six weeks has been £380:19:0. The sales of the Journal during the twenty-six weeks have produced £35:15:5. There have likewise been sold, but not yet paid for, Journals to the amount of £12:15:5. The value of the stock in hand may be considered as £54:12, being one-half of the annual subscriptions of 184 members, who may be expected to join before the conclusion of the year. It therefore follows that the money available for

Journal purposes during the first six months of the year is			
£1,390:6:10, viz.,	£	s.	d.
Proportion of subscriptions of members,	828	14	6
Estimated subscriptions of new members	54	12	0
Advertisements and sales	447	0	4
	1,390	6	10

"With regard to the expenditure for the six months, the amount for printing, as per estimate, with extra charges for tables, has amounted to £401:14:6. The actual price of paper and stamps has amounted to £404:10:11. The salaries of publisher and commercial assistant for the half year have amounted to £30:0:0: the items will be found classified in a table appended to this letter. I have kept considerably within the limits assigned to me by the Committee in expenses incurred for literary contributions and woodcuts. The saving in this department has resulted principally from the outlay for leading articles having been only one guinea, whereas a considerable expenditure was contemplated in that department. The Committee authorised an outlay of £100 for literary assistance during the first half of the year; but the expense actually incurred has amounted to only £58:17:6. I do not recommend so much parsimony in this department as either necessary or safe for the future.

"The mode in which the sum of £58:17:6 has been expended next demands attention. After careful deliberation, and consultation with Dr. Cowan and others, it appeared to me that the most economical and most efficient mode of obtaining a steady supply of the best literary assistance was to offer to Dr. Alexander Henry, of whose thorough competence for the work I had had ample opportunities of judging, the sum of £75 per annum for a certain amount of literary labour. In this way, by combining the two appointments of literary and commercial assistant, I am satisfied that a very large saving has been effected, and a plan adopted which has in every way worked well. The expenditure for other contributors has amounted to £14:14, which

has been shared among five individuals. Although numerous woodcuts have appeared in the Journal, the wood engraver's account for the half-year amounts to only £8:13:6; of which £1:7:6 has been paid by authors.

"It therefore appears that the expenses incurred in the production of the Journal for the first six months of the year have been £1280:4:9, viz.;

Commercial department and miscellaneous expenses -	1007	14	9
Editor's salary, payments for literary assistance, and woodcuts -	182	10	0
	£1280	4	9

"The excess of income over expenditure may thus be stated as £50:2:1. A small reduction may have to be made for bad debts; but, as the advertisements and sales are cash or quarterly transactions, the loss, if any, will be exceedingly small. The account of expenditure contains sums of money for preliminary expenses connected with fitting up the Journal office, etc., which will not again occur. In the subjoined table will be found a more detailed statement of the facts which have been presented to your view.

"The returns from advertisements far exceed the estimated amount which the Committee originally dealt with in making their calculations. It was naturally supposed that, as the Journal did not circulate much through the book trade, it was not likely to receive many advertisements from publishers. The Association Journal is now, however, becoming every day more and more recognised as one of the best media for advertisements; and, by means of an inconsiderable outlay, its sterling value might be so made known as to raise the income from advertisements to four times its present weekly average. The repeal of the advertisement duty, while it will be found by advertisers to be a great boon, will likewise be felt an equal benefit by the Journal.

FINANCIAL STATEMENT OF THE JOURNAL FOR THE SIX MONTHS ENDING 1st JULY 1853.

[Account made up to 4th August 1853.]

* Since the 4th of August, when the above account was drawn up, a considerable number of members have joined: and some of the stock has also been sold.

From the above statement, it appears that in liquidation of £1280:4:9, expenses incurred, £902:0:4 has been paid, leaving an unpaid balance of £378:4:5. To meet this, there is £428:6:6; viz., Cash, £105:9:6, and Assets, £322:17:1.

I have examined the above, and seen the vouchers.

JOHN ROSE CORMACK.

"Since the commencement of the year, there has been a steady weekly influx of new members, as well as an increase in the average weekly receipts from advertisements and the sale of the Journal. Taking, therefore, into consideration the financial aspect of the Journal as represented in the subjoined account, in connexion with the circumstances just mentioned, the financial success of the Journal scheme is manifest. It must, however, be borne in mind that present prosperity can be sustained only by increased vigilance in regulating the expenditure by the income; and that permanent safety cannot with propriety be considered as obtained, until either the Association has a reserve fund, or until the Journal can maintain a considerable floating balance.

'I am, gentlemen,

'Yours very faithfully,

'JOHN ROSE CORMACK.'

"Your Committee have reason to know that the removal of the Journal to London has been the means of causing a great increase of members to the Association, including a very large number of the most respected and influential members of the profession both in town and in country, in Scotland as well as in England. The increased expense, it will be seen, is met by the increased income from all sources.

"Your Committee have much pleasure in expressing their high satisfaction with the manner in which Dr. Cormack has conducted the literary department of the Journal; and also their obligation to him for his great trouble and sacrifice of time in satisfactorily organising the business arrangements.

"They also would express their approbation of the manner in which the printer and publisher of the Journal have performed their duties."

(Signed)

CHARLES COWAN, M.D., *Chairman.*

JAMES EDWARDS, M.D.

W. A. GREENHILL, M.D.

GEORGE WEBSTER, M.D.

THOMAS HUNT, *Secretary.*

Mr. W. H. MICHAEL had much wished that the Report of the Journal Committee should have been read before the Report of the Council was adopted; especially as a right appreciation of the financial aspect of the Journal must exercise so great an influence on the question raised by Dr. Tunstall with reference to the continuance of the *Transactions*. In deference to the evident wishes of this meeting, he had not seconded the amendment which Dr. Tunstall proposed; but he, nevertheless, conceived that he was perfectly in order in now considering the subject of the financial position of the Association in relation to the Journal. He could see no reason to doubt but that under good management the Journal and *Transactions* may both continue to appear; and he, for one, should certainly regret were we to lose all hope of publishing, under the auspices of the Association, the valuable papers read at its anniversary meetings; some of which, from their nature, are not suitable for a weekly journal.

But in viewing this question—and without the slightest wish in any way to impugn the accuracy of the Council Report—it seemed to him that while the figures in themselves were perfectly true, yet from the manner of the grouping they might lead to untrue inferences, and might make it appear that the annual subscriptions of members were much more largely drawn upon than, upon examination, would be found to be really the case. He had most carefully examined and made an abstract of the Journal accounts, which, with the president's permission, he would read to the meeting. First, it would be found, from the printed financial statement which he held in his hand, that the total cost of printing and publishing the Journal for the first six months of the year amounted to £1280 : 4 : 9. From this must be deducted £35 : 15 : 5 received from sales of the Journal, and £248 : 12 : 10 received for advertisements; as well as a further amount of debts owing to the Association for sales and advertisements of £102 : 12 : 1, from which, however, as they were debts which, however good, still admitted the possibility of non-payment, he would, to ensure the avoidance of fallacy, deduct £22 : 12 : 1 as possibly non-payable, leaving the sum of £140. The sums realisable on the profit side of the Journal account would then be

Receipts for Sales	35 15 5
Receipts for Advertisements	248 12 10
Due for Journals and Advertisements ..	140 0 0

£424 8 3

There were also other expenses which had occurred in the last six months, and which happily could never again be a charge to the Journal. The total repeal of the advertisement duty

would take from the payments the further sum of £63 : 11 : 6. To this must be added those preliminary and extraordinary expenses inseparably connected with the establishment of any new concern or business, and which in the present instance were

Preliminary expenses	31 3 2
Editor's Letter Box	1 5 0
Petty Expenses of Journal Committee....	1 7 3

£33 15 5

This, with the sums already mentioned, made a grand total of £521 : 15 : 2 to be deducted from the working expenses of the Journal for the first six months; leaving the cost of the Journal to the Association in the future six months, if there be no increase of sales or advertisements, to be estimated at £758 : 9 : 7, or about £1500 per annum; a sum which little exceeded the amount named by Dr. Cowan at the Oxford meeting as the probable annual cost, and very different from the figures which at first sight appeared as the cost from the Council Report. But, continued Mr. Michael, could we believe that the Journal is to remain stationary in the immense progress it had already made? The happy opportunity which the repeal of the advertisement duty afforded for tradesmen to offer articles for sale, and to others in and out of the profession to make known their wants, rendered it certain that the revenue from advertisements must be largely increased. He had been quite astonished at noticing the large amount which had been already received for advertisements, taking into account the non-connection of the Journal with any bookselling or trading firm, and the difficulties and oppositions which every new undertaking of this character must have to encounter. From its past success he could not but believe that, when it became extensively known that the Journal had a guaranteed circulation of two thousand weekly,—penetrating alike to the rich man's library, and to the cottage of the hard-working surgeon; to the iron mines, and to the mountain fastnesses of our picturesque Principality—he felt that the number of advertisers, and the income accruing, must be very greatly augmented; and that the Journal required but to be generally known, to be universally adopted as the best advertising medium for subjects addressed to the medical profession. And here he would state that, in looking over the weekly accounts, which he held in his hand—accounts kept in the most accurate and business-like manner, where, under printed heads, every penny of expense was tabulated and set down for the inspection of any member of the Association—he found that above £40 in stamps and paper had been expended for gratuitous distribution of the Journal: a large sum, which, if saved, would still further diminish the actual cost. He believed, however, that here parsimony might not be true economy; and that, to secure the advantages derivable from increased knowledge of the Journal, it would be necessary occasionally to recur to these expenses. Looking at the unparalleled number of new members who had joined the Association during the present year, amounting to 429—21 of whom had joined during the few days of this month,—and to the fact that others, who had not yet joined the Association, had been proposed, he could not but feel that, while the Association was in the most hopeful and healthful condition, much of this great accession must be traced to the direct influence of the greatly improved tone and character of the Journal—an improvement universally felt and acknowledged by all the members of the Association with whom, by his position as District Secretary, he was daily brought in contact. This fact, indeed, he had used as an inducement to gentlemen to become members of the Branch to which he was attached; and he had found it generally responded to. [Cheers.] He could not but tender his hearty thanks to Dr. Cormack—and it was an expression of feeling in which, he was assured, every member would join—for the very able manner in which he had conducted the business of the Journal for the past six months; for, by the high tone which pervaded its articles, it tended not only to increase the interest attached to it as the organ of this Association, but to improve the status and the knowledge of the profession. [Cheers.] It was not to be supposed that any man, however talented and able, however competent and high minded, could on all occasions, and upon all subjects, please the various minds who would peruse his writings; for an independent thinker must strike out for himself his own path, and must pursue with earnestness, looking neither to the right nor the left, and fearing and courting no influence, however great, that way which a desire to benefit his profession might dictate to him. He looked forward to the time when the Association would be the means of improving the condition of the hard working medical practitioner; for he believed that a continuance of the Journal,

characterised by its present high intellectual and moral bearing, could not be without influence on the public mind, in teaching them how much they are indebted to the medical profession, and what that profession should receive at their hands. He had, therefore, great pleasure in moving—

“That the Report of the Journal Committee be received and adopted; and that the Committee be requested to continue their labours.” [Cheers.]

Dr. LINGEN, of Hereford, had much pleasure in seconding the motion.

Mr. NORMAN, of Bath, would not oppose the motion; he thought that in all the circumstances it was a proper motion: but he must be allowed to say, from the facts and figures which had been brought forward, that it would be necessary to take care that the expenses of the Journal were kept within legitimate limits; and that it did not lead the Association into debt. The Report of the Council on this point ought to be duly weighed.

Dr. TUNSTALL, of Bath, said that it appeared that the Association, and therefore the Journal, was at present depressed by an enormous amount of arrears of subscriptions; no less a sum than £1093. Now, he thought that such a state of affairs ought not to be, and need not be, if there was a proper machinery for collecting subscriptions. In the Bath and Bristol Branch, of which he was a member, there was not one of their hundred and thirty members in arrears; and this ought to be the case in every other district. He was surprised to see that there was such a heavy arrear of unpaid subscriptions due for the present and previous years. Every member who wished to see the Association flourish, and to see the Journal maintained in its present efficient and influential form, ought to exert himself to assist the Secretary in the collection of subscriptions, and also to impress the members generally with the duty of regularly paying up their subscriptions at the date when they become due. There was a rule of the Association, by which a very hurtful latitude was allowed in this matter; viz., that if arrears were not paid up within three years, the Journal should be discontinued: and thus some had actually been for three years receiving the Journal gratuitously. The existence of arrears, and its cause, had been, for several years past, regularly brought forward at the annual meetings; and yet each year they found themselves in the same position as on the previous year. As had been stated, the Journal was satisfactory to the profession; and he thought that, if a better system of payment were adopted, it would be quite practicable to continue the Journal in an efficient form, without losing their highly valuable annual volume of *Transactions*.

Mr. BOWLING, of Hammersmith, said that a paid collector would very soon bring up the arrears.

Dr. MCINTYRE, of Odiham, thought that the Journal ought not to be forwarded if the subscriptions were not duly paid. He thought, at all events, that when a member was three months in arrears, his Journal should be stopped; which would be a hint to him to remit his subscription. He would be inclined to move a resolution to that effect. To be supplying hundreds of Journals gratuitously every week was an expense, which of course the Association could not support.

Sir CHARLES HASTINGS said, that the proposition of Dr. McIntyre would interfere with the rights of members, and abrogate a law. As no notice of motion had been given, the improvement in the law suggested by Dr. McIntyre could not now be entertained.

Mr. SODEN, of Bath, fully admitted the great improvement which had lately taken place in the Journal, since it had been under the able superintendence of Dr. Cormack. He, however, very much questioned the propriety of the introduction into its pages of such irrelevant subjects as the opening the Crystal Palace on Sunday. He had been requested by several gentlemen in Bath to state that this was also their opinion on the subject. He did not for a moment call in question the great ability with which the Journal was at present edited; but he doubted very much the propriety of making it a vehicle for such extraneous views as he had referred to.

Dr. COWAN wished to say a few words before the motion was put from the chair. As regarded the financial aspect of the Journal, he had little to add to the admirable exposition of Mr. Michael. He (Dr. Cowan) was one of those who had advocated the removal of the Journal to London; and, indeed, on him had devolved the greatest amount of the responsibility which had been incurred in advocating and carrying out that great change. He had thought that the Association might, without any increase of their subscription, get a better Journal—a weekly in place of a fortnightly Journal—and a Journal of the highest talent, thoroughly up to the science of the day. All this had been accomplished; and it was to him a matter of the highest

gratification to see the approbation with which the high tone and scientific value of the *ASSOCIATION JOURNAL* was regarded. And here, he (Dr. Cowan) would pay off an old score. He had acted altogether apart from selfish motives. Personally, Dr. Cormack was not known to him when first he looked about for some one capable of carrying out the project. It was Dr. Cormack's public character and reputation alone which had recommended him to Dr. Cowan in the first instance, and ultimately to the Committee; and the experience of the last seven months had demonstrated that a better choice could not have been made. He did not think that there was any other man who could have done for the Association what Dr. Cormack had done, in his organisation of both the literary and the commercial departments. (Cheers.) He hoped that every member of the Association would exert himself to the utmost of his power in encouraging and sustaining the efforts of the editor; and in increasing the number of members by making known the merits of the Journal and the advantages of belonging to the Association. Hitherto the meetings had been the chief inducement to join the Association; but now every member could likewise have at his own home more than an equivalent for his subscription. He had no fear of its being ultimately found necessary to discontinue the *Transactions*: but, as compared with the Journal, he regarded that as a minor consideration.

Dr. CONOLLY, of Hanwell, felt that it was extremely difficult to make any observations upon this subject, without subjecting himself to the imputation of saying what was discourteous to the editor of their Journal. He had always opposed the removal of the Journal to London; and he thought that if its weekly publication interfered with the issue of a volume of *Transactions*, the time had arrived when they ought seriously to consider the propriety of returning to the old fortnightly periodical. As regarded his friend Dr. Cormack, the editor of the Journal, he fully concurred in what had been said of his learning, talent, and zeal, in conducting their Journal; but, having said this much, he hoped he might be allowed freely to say, as a member, that the Journal was deficient in general news and minor articles. The essays and letters of members occupied a disproportionate amount of space. In general intelligence, the *Lancet* and *Medical Times* were decidedly superior; and he thought that there ought to be improvement made in this department. He was far from thinking, however, that a weekly Journal, or a Journal at all, was necessary for the prosperity of the Association.

Dr. COWAN. No other man could have done what Dr. Cormack has done for the Journal. His experience, his talents, his perseverance, and his good feeling, had all been called into active exercise. As a member of the Journal Committee, he knew this: and therefore he (Dr. Cowan) could not sympathise with the remarks of Dr. Conolly.

Dr. SIBSON, of London, said, they must all feel that they had an editor who discharged his duties with the greatest ability, and the strictest honour; and one who had succeeded in giving general satisfaction. This he said, without by any means approving of all the sentiments which had been expressed in the Journal. As regarded the publication of *Transactions*, he felt that this was one of the most important features of the Association; and he was extremely happy to find that there was a fair prospect of both the Journal and the *Transactions* going on together.

The PRESIDENT (after a few words from Dr. Conolly) said that that gentleman had in no way called in question the ability and zeal of the editor.

Sir CHARLES HASTINGS said, that he concurred with the sentiment which had been expressed, that it was both undesirable and unnecessary to go back upon the past, and reopen former discussions. He would remark, however, that what he had foretold at Oxford, was now found to be true; and that a very much larger expenditure had been incurred, than had been stated to be necessary by his sanguine friend Dr. Cowan, who had then assured them that for £1,300 or £1,400, they might have a weekly Journal. Now, the expense had just been doubled. The expenses of the first six months amounted to about £1,300: and twice £1,300 is £2,600. His sentiments on the subject were so well known to most of the gentlemen present, that he would not have intruded himself upon the meeting, had not Mr. Michael called in question the accuracy of the figures in the Report of the Council: whereas he was prepared to demonstrate that every figure was strictly correct. There was a slight discrepancy in one amount. The Council had taken the figures as they had been forwarded to them by Dr. Cormack; and it was for Dr. Cormack to explain the discrepancy. It could not be tolerated that the statements of the Council should be con-

sidered incorrect, when he well knew them to be strictly correct, and, moreover, when they had been unanimously passed by that meeting; and to be, as regarded the Journal, exactly those which had been supplied by Dr. Cormack. He held in his hand Dr. Cormack's own statement.

Dr. CORMACK. I should like to see that paper. [Looking at the paper.] I see no discrepancy in the statement sufficient to affect any argument. This statement was sent as a draft supposed to be correct; but the accounts of receipts and payments were afterwards brought down a few days later; and two small payments on behalf of the current half year were removed to next account. I afterwards forwarded the correct summary, as now printed, and before the meeting.

Mr. MICHAEL must be allowed to say that he never even insinuated that the figures in the Report of the Council were inaccurate. What he had said was, that true accounts might be made to speak untruthfully or ambiguously, from the way in which they were placed in relation to each other.

The PRESIDENT. Mr. Michael, you have the right of reply; but I cannot hear you at present.

Sir CHARLES HASTINGS was, for one, not so very sanguine as his friend Dr. Cowan. He ventured to say that, unless they could raise their numbers to two thousand five hundred, they could not hope to have a volume of *Transactions* annually.

Dr. COWAN. We will raise them above that.

Sir C. HASTINGS. Unless we have this increase of members, the present scheme could not be regarded as either safe or successful. It would not do to calculate assets as receipts; and that was what had been done by the Journal Committee. There was a fallacy in saying that £248 had been received for advertisements; for advertisements had cost £105 expenses—expenses of a kind which had never been incurred at Worcester: so that the real receipts for advertisements had been only about £143. This was the way in which the accounts must be looked at. His candid opinion was, that they were not in so favourable a position as some gentlemen seemed to imagine. As to the great accession of new members, he could not ascribe this to the Journal. Some might have joined on that account: but in Swansea and its neighbourhood, for example, the increase of the Association was owing to the establishment of a new Branch; and in Manchester, the influx was owing to the prospect of the anniversary being held there next year. Then, among the new members, there might be a great number of defaulters—gentlemen who would say, after a time, "I do not wish to belong to your Association: I do not care about your Journal"; whereas, the truth probably would be, that they did not care to pay their guinea. Sir Charles said, that he considered it his duty as Treasurer, to place these facts before them. Before sitting down, however, he must be allowed to express his praise of the spirited manner in which the Journal Committee had carried out their project. He felt, in common with every other member of the Association, greatly indebted to them for the time and attention they had bestowed upon this work. He would also bear his testimony to the skill and ability with which Dr. Cormack had edited the Journal: and he hoped that, in the remarks which he had made, no one would suppose that he had intended to disparage the labours of that gentleman. He had only thought it right to give his candid opinion upon the matters which had been considered that morning; and he had also, as President of the Council, thought it his duty to vindicate the strict accuracy of the Report of the Council. He had no wish to urge them not to pass the resolution; he thought it was a very proper resolution: but he thought that increased expenses must be well looked into. [Cheers.]

Mr. W. H. MICHAEL, having been called upon by the President, replied. He concurred with Sir Charles Hastings in thinking that the Journal expenses ought to be curtailed if it were possible; but he believed that economy in this department could not be in any degree promoted by cramping the editor, by withholding the necessary supplies. A small outlay was no test of economy; it might be the greatest possible extravagance. If the Journal is to be cheaply carried on, it must be so liberally nourished by the Association as to be able as at present to yield a large portion of the funds by which it is maintained. It seemed to him that Sir Charles Hastings was stating an entire fallacy when he said that the expense of the Journal was £2,690 a year. If a man spent £1,280 in six months, and £400 were returned to him out of that amount, it could not truly be said of him that he had lived at the rate of £2,560 a year. The fact was, the man would only have been living at the rate of £1,760 a year: and this was the position of the Journal; with this advantage, that for the future, certain heavy expenses, which had been necessarily incurred, would not be repeated.

Sir CHARLES HASTINGS must correct Mr. Michael. He (Mr. Michael) was building a financial statement upon monies not yet received, and upon measures of economy not yet accomplished. His financial statements were entirely visionary. The Journal income as given in the Council Report was all that could be relied on, inasmuch as it was all that had been received. The accounts of tradesmen could not be paid by visionary sums of money.

Mr. MICHAEL. Is it visionary to say that, as the duty on advertisements is repealed, we cannot have £63:11:6 in our accounts of the current half-year for advertisement duty?

Sir CHARLES HASTINGS. True: but we are sure to have some equivalent source of expense.

Mr. MICHAEL. Well: that is certainly visionary finance. [Laughter.] The Journal accounts as exhibited in the summary and in the weekly statements, seemed to Mr. Michael so clear, so circumstantial, and so satisfactory in all their details, as not to warrant the application of the term *visionary* to the simple deductions from them which he had submitted to the meeting. As there was no amendment before them, it would not be necessary to recapitulate his former remarks.

The PRESIDENT then put the resolution, which was carried unanimously.

REPORT OF THE MEDICAL REFORM COMMITTEE.

The following report was read by Mr. GEORGE HASTINGS, Secretary to the Committee.

MEMBERS OF THE COMMITTEE. Sir Charles Hastings, M.D., D.C.L.; A. Robertson, M.D.; G. Webster, M.D.; Mr. Nunnely, F.R.C.S.; Mr. Noble, F.R.C.S.; Mr. Bottomley, F.R.C.S.; Mr. Walsh, F.R.C.S.; Mr. Cartwright, M.R.C.S.; Mr. Southam, M.R.C.S.; Mr. Bree, M.R.C.S.; Mr. Stedman, M.R.C.S. Mr. G. Hastings, (Secretary.)

"Your Committee, in resigning the trust that was imposed on them at the annual meeting at Oxford in 1892, desire to bring fully before the Association the measures which they have taken to fulfil the duty assigned to them. Your Committee have held five general meetings of their whole body, besides those of the sub-committees which they have from time to time appointed; they have sent deputations to Government and to several medical corporate bodies, and have received reports from them; they have constantly communicated by letter with their secretary and each other; and they have given a deep and anxious consideration to the measure submitted to their care.

"They conceived that their first object should be to ascertain the opinions of the different medical corporate bodies in reference to the draft measure; and they accordingly empowered their secretary at their first meeting to communicate by letter with the Universities and Medical Colleges of Scotland and Ireland. With those of England, another and more direct mode of communication was adopted, as will be afterwards shown in this report. At the same time a sub-committee was formed, who were directed to go carefully through the draft Bill, and to report to your Committee any alterations that might appear advisable to be made. In accordance with suggestions made by these gentlemen, and after the most careful deliberation on the part of your Committee, it was resolved to make several emendations in the bill, of which the principal were, the omission of the clauses relating to the Provident Fund, and the introduction of a provision compelling the proposed medical council to publish annually a statement of their accounts. At the same meeting, which was held on the 5th of October, a resolution which had been passed by the council of the National Institute, relative to the bill, was read to your Committee. Anxious to ascertain as far as possible the opinions of the whole profession on the subject which engrossed their attention, your Committee sent some members of their body to confer with the above named council; but unfortunately the result of that interview was not as favourable as your Committee had hoped it might be.

"At the same time your Committee determined to send a deputation to the medical bodies of Scotland, with whom they had already corresponded without any decisive result. Accordingly, in the beginning of November, two members of our body proceeded to Edinburgh, and there had the honour of an interview with the representatives of the Royal Colleges of Physicians and Surgeons of Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow. The result of this interview was satisfactory in the highest degree; so much good feeling was exhibited by our Scotch brethren, and so much desire was felt on both sides to waive minor differences for the sake of the great object in view, that arrangements were made, and shortly afterwards ratified by your Committee, by which the cordial cooperation

ation of the Edinburgh Colleges was secured for the Bill of the Association. This result was obtained, as your Committee believe, by keeping steadily in view the principle with which they started; viz., that in all those parts of the measure which related to Scotland and Ireland, the wishes of the profession in those portions of the United Kingdom should be as far as possible deferred to. Your Committee were at the time under the impression that all the medical corporations of Scotland were united together in the cause of medical reform; but they have learned with regret that a misunderstanding has since arisen between the Colleges of Edinburgh and the Faculty of Glasgow, in reference to the constitution of the Examining Board. Your Committee can only express their hope that this difference may be speedily and amicably arranged. Your Committee are happy to be able to state that from the Royal College of Physicians of London they have received the utmost courtesy and attention. That ancient corporation have throughout the negotiations carried on with your Committee, evinced an anxious desire for the welfare of the profession, and have candidly stated any objections they entertained to the proposed measure. A statement of these objections was forwarded to our secretary by the Registrar of the College, and your Committee are happy to state that they were able to accede to all, or nearly all, the suggestions contained in this document. A deputation from our body had subsequently an interview with the authorities of the College, and your Committee believe that there is now no point of any importance on which any difference exists between the College and themselves; and they have the assurance of the Registrar that the Bill of the Association, in its amended form, would harmonize completely with the provisions of the intended new charter of the college, and would effect a greater amount of practical improvement, and produce a better chance of a permanent settlement, than any plan that has hitherto been proposed to the medical profession of the United Kingdom.

"Your Committee are sorry to be obliged to state that from the Royal College of Surgeons of England they have not received either the same assistance or the same candid objections. Indeed, at the two interviews which deputations from your Committee have had with the authorities of the College, some difficulty has been experienced in arriving at any knowledge as to what the objections of the Council of the College are, further than that they have a general objection to medical reform in any degree. Your Committee trust that such objections, so alien to the feelings of the profession in the present day, will shortly be laid aside, and that the Council of the College may see the wisdom of acting more in accordance with the opinions of their constituents. But, should this hope not be realised, your Committee feel assured that the voice of this powerful Association, backed by that of the great majority of the profession throughout the United Kingdom, cannot fail to make itself heard within the walls of Parliament against any opposition.

"Objections having been made to portions of the Bill by some members of the South-western Branch of this Association, your Committee were desirous to ascertain their precise sentiments on the subjects; and our secretary had accordingly an interview with the President of the Branch and some others of its members, at which their suggestions were reduced into three heads, and put into writing for the information of your Committee. With regard to two of these points, the objections urged are met by alterations that have been introduced into the measure; but as to the third, which was a proposition that a certain number of the proposed council should be provincial as opposed to metropolitan practitioners, your Committee felt unwilling to accede to it. It is no doubt most desirable that the provincial profession should be adequately represented in any body governing the profession, and a provision to facilitate the appointment of provincial practitioners by giving a mileage in addition to the fee for attendance at the meetings of the council, has been introduced into the Bill; but it appears inexpedient to fix the exact proportion which they should bear in the numbers of the council.

"Your Committee have received a communication from the South-eastern Branch of this Association, urging the importance of having upon the proposed council a certain number of members elected by the whole profession. Your Committee are fully alive to the importance of the representative principle being carried out as far as possible; and though they found on deliberation that there are many practical difficulties in the way of such a mode of election, they consider that this subject, which is one entirely of detail, may fairly be urged on the consideration of Parliament when the measure is introduced into that assembly.

"Your Committee having obtained, as before mentioned in this report, such powerful cooperation in their exertions, and feeling assured that the Bill they had prepared had received the support of the great majority of the profession, proceeded in March last to place the measure in the hands of Lord Palmerston, as Secretary of State for the Home Department, and to urge on his lordship the necessity of taking up, as a member of the Government, the subject of medical reform. Your Committee were accompanied on this occasion, by the Presidents of the Colleges of Physicians and Surgeons of Edinburgh, by many eminent members of the Association and the profession, and by about sixty members of Parliament. The deputation were most courteously received by his lordship, who expressed his determination to turn his attention as soon as possible to medical reform. On a subsequent occasion your Committee had the honour of an interview with the Earl of Aberdeen, as head of Her Majesty's Government, who also expressed himself as deeply impressed with the importance of the subject in reference both to the profession and the public. Your Committee are happy to be able to state with confidence that early in the ensuing session of Parliament a Bill to promote medical reform will be introduced by Lord Palmerston. Your Committee have, therefore, in a great measure fulfilled the trust imposed on them. They have succeeded in preparing a measure which commands an unparalleled amount of sympathy and support from the profession at large, and they have also succeeded in drawing the attention of Government to that measure, and in thus preparing the way for its being laid on the table of the House of Commons. Whether it will pass into law will chiefly depend on the exertions made on its behalf; and on this head your Committee are sanguine in their expectations. An association of metropolitan practitioners has been formed in London for the purpose of supporting the Bill, and has already rendered valuable aid. Nor do your Committee doubt that when the measure shall be brought before Parliament the strongest efforts will be made by the profession throughout the kingdom to obtain its enactment into law. Considering the influence which the profession can exert, and the parliamentary support which your Committee have already been able to obtain, there can be little question that the noble Secretary of State for the Home Department will find himself powerfully supported in his attempts to carry out the measure.

"Your Committee entertain a confident hope that the members of this Association will see the wisdom of waiving any minor differences as to details, as your Committee have themselves set the example of doing, and of joining heartily together for the good of the profession in obtaining a settlement of this long agitated question; and while they congratulate the Association on the progress that has been made in the great cause of medical reform, they urge upon the members not to relax their exertions until they have achieved the object of their hopes, and placed the interests of the profession upon a broad and durable basis.

CHARLES HASTINGS, *Chairman.*"

Mr. NORMAN proposed a resolution, signifying the confidence of the meeting in the intentions expressed by Lord Palmerston; and also proposing that the Committee should be reappointed.

He said that the Association, and indeed the profession at large, was deeply indebted to Sir C. Hastings and the other members of the Committee for the energy with which they had discharged the difficult duties which had been entrusted to them. They also owed many obligations to Mr. George Hastings, for the able draft bill which he had prepared. It was not to be supposed, and indeed it was not desired, that the bill in its present form should be adopted unchanged by the legislature. The Association was pledged to great general principles, but not to details. A measure satisfactory to the profession and beneficial to the public could not now be much longer delayed; and if the public could only be made to understand how much their interests were at stake in the just settlement of this question, he believed that the House of Commons would be obliged to proceed with medical reform upon just and liberal principles. The suppression of the infamous practices of certain unqualified practitioners would be an obvious benefit to the public.

Mr. SODEN seconded the resolution.

Dr. BLACK, of Bolton, concurred in the resolution. He did not, however, believe that acts of parliament could crush empiricism, or protect the public from illegal practitioners. Large sections of the public would go on as now, patronising all kinds of quacks as their own appointed medical advisers; and when

one medical delusion was dispelled, another would always be ready as heretofore to succeed it.

Dr. DAY complained that the Committee had only conferred with three Scottish licensing bodies, the College of Physicians of Edinburgh, the College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow.

Mr. G. HASTINGS said that the bill had been sent to the secretaries of all the Scottish Universities and Colleges in common with those of England and Ireland.

Dr. DAY was not opposed to the general principles upon which the Association had been endeavouring to settle the question of medical reform; but notwithstanding what the secretary had stated, he must say that the University of St. Andrew's had not been consulted during the progress of recent negotiations; and he knew that Aberdeen had been in like manner neglected. In arranging the details, it was essential to success that all the licensing bodies should be consulted.

Mr. PAGET, of Leicester, differed from Dr. Black as to the probable effects of a good bill in restraining illegal practice. He thought that the College of Physicians ought not to get their charter before the general profession obtained a measure of reform and protection. The charter might be of such a nature as to interfere with such a reform measure as would be acceptable; and both ought therefore to pass through Parliament simultaneously.

SIR CHARLES HASTINGS explained that the College of Physicians, far from opposing the Association, were friendly to them. At the same time, he might inform Mr. Paget that it had been determined by Lord Palmerston that the College of Physicians was not to have its charter this session.

Mr. PAGET: I am glad to hear it.

The PRESIDENT then put the resolution; and declared that it had been carried unanimously.

EXPENSES OF THE MEDICAL REFORM COMMITTEE.

Some conversation arose as to the way in which the expenses of the Committee were to be defrayed. It was ultimately decided, upon the suggestion of Sir C. Hastings, that as the Association had voted £200 last year to the Medical Reform Committee, they could not, with their present financial responsibilities, grant an additional sum this year; but that a sufficient sum might be secured for the use of the Committee by opening subscription lists. This was done in the course of the afternoon, when a considerable amount was obtained.

In an early number we shall report the conditions and the result of the subscriptions. At present, we are not able to communicate exact information on these points.

[The meeting adjourned a few minutes after one, and re-assembled at two o'clock.]

EIGHTEENTH ANNUAL REPORT OF THE MEDICAL BENEVOLENT FUND, BEING FOR THE YEAR 1852-3.

Mr. NEWMAN, Treasurer and Secretary to the Fund, read the following report:

"The Committee of the Medical Benevolent Fund, in rendering the annual account of their proceedings, desire to record their thankfulness for the measure of prosperity which has attended their labours.

"The year has been one of unexampled trial and difficulty; their loss in the number of their original subscribers has been *great*; the misapprehension of their object has been *great*; and yet, in consequence of the accession of new subscribers, the entire amount of that income has not been lessened, and they have been enabled to relieve the urgent cases of distress brought before them, not, indeed, according to their wishes, but still with a degree of efficiency which has proved the cup of cold water to the fainting soul,—the morsel of bread to the famishing; and thus, in many instances, has been that seasonable boon, which has saved the wretched brother from starving, and has rescued the widow and the orphan from the miseries of the Union-house, and the total destitution of pauperism.

"Your Committee have witnessed, without feelings of rivalry, the success of a newly formed institution; and they have even rejoiced in that success, which has greatly arisen, no doubt, from its offers of a patronage which you could not hold out, and while the only motive which you could offer to your subscribers is the pure luxury of doing good for its own sake.

"With every kind wish for the success of the Benevolent College, your Committee are anxious to place before you the essential difference of the two institutions; and they are desirous that you should bear in mind the fact, that the College cannot relieve the cases which are continually presented to your notice; that the instances of casual destitution in professional life are

utterly beyond their province; that they are therefore frequently sending cases to you for relief which they cannot aid; that the real misery of the profession is left untouched by their arrangements; and that if their success should be as complete as their best friends hope, the necessity for your institution is not superseded—but that under the most favourable circumstances, there must remain a mass of misery which is *unrelieved* and *unrelievable*, except by a purely charitable institution such as the Benevolent Fund, which stretches out its hand to palliate distress, asking for nothing again—asking for no pecuniary resources in order to present a title to relief—asking for no peculiar claims except the established fact of the existence of misery and destitution among the regularly educated members of the profession, and that they should be persons of unblemished moral character.

"Your Committee therefore regret that many of their subscribers should have withdrawn their aid, because they had contributed to the Benevolent College; they regret that many others should have not subscribed, because they intended to support the Benevolent College; and they are particularly anxious to impress upon you the fact, that the Benevolent College is *unable* to relieve the cases which come under your notice; and that, in the most favourable circumstances, it is utterly impossible for the College to supersede the necessity for your fund, which becomes every year more apparent, and which they conscientiously believe a few years will demonstrate. Hence, they earnestly implore their subscribers to strengthen their hands, to renew their subscriptions, to increase their efforts, to augment their annual sums, and to enlist the feelings of their own hearts and their friends in their support.

"It is much to be regretted that a considerable number of old friends should have been thus alienated; but it is equally a subject for rejoicing that a large accession of new subscribers has been obtained, so that notwithstanding every difficulty the ultimate amount of your income has not been lessened. The amount of subscriptions for the year ending June 30th, has been £891:3:0, against a sum of £655:8:7 in the previous year, exhibiting an increase of £234:14:5 on this item, and leaving a balance due to the treasurer of £22:2:6.

"Your Committee beg to direct your especial attention to the economy with which your institution has been conducted, and they challenge a comparison with any other similar charitable society, in which so great an amount of real good has been effected at so small a cost; thus showing that almost the entire sum collected by subscriptions has been devoted to the exclusive relief of suffering humanity.

"The number of cases aided has been seventy, at a cost of £654, or about £22 less than the last year. The cause which will explain this difference is, that the amount of subscriptions has been somewhat smaller, and the number of your applicants somewhat larger. This result has been brought about, not by the diminished urgency of the cases relieved, but by the inadequacy of your funds. Your Committee are particularly anxious to impress upon you this fact, as well as that during the whole year they have been indebted for the payment of their grants to the advances of their treasurer; and they would remind you, that this state of things ought *not* to be, and cannot be expected to continue. They therefore exhort all their subscribers to remove this stain from your institution by increased energy and promptitude, and increasing self-sacrifice, and so to place your fund upon a pedestal of security, which will save it from being dependent upon the means, or the will, of a generous treasurer.

"It is, however, gratifying to record the increasing number of subscribers, to fill up the above mentioned vacancies; and they earnestly request the renewal of subscriptions, while they exhort their old subscribers to obtain fresh supplies from their friends and connexions, in order to relieve a distress which no other institution can effect; and thus to place your own fund upon a pinnacle of security, which neither the waves of adversity, nor the winds of changing circumstances, can impair.

"It is a fact, that for a few years your institution will yet require peculiar care and attention; but under its present auspices, if permitted to retain them, it is confidently hoped that in that period its efficiency will be proved, and that it will be shown to be the only society which can relieve its own department of casual professional distress.

"With these hopes, your Committee take leave of this part of their Report, imploring that you will enable them to realise their anticipations, and to establish your fund upon a rock which will not require the same amount of anxious care and unremitting solicitude that now bear upon their movements."

"By a reference to the cash account, you will find that your

trustees have invested a further sum of £229:19:6 in the purchase of Bank Stock; leaving a balance from the Donation Fund of £9:6:6 in the hands of your treasurer. This sum is not available for the relief of present distress, and the amount due to your treasurer from the Subscription Fund is £22:2:0, or about £18 more than at the commencement of the last year.

"The number of your annuitants has been increased in proportion to the increase of your annual income—the number is now seven; and your Committee rejoice to inform you that a legacy of £500 has been left to your fund by the late Mr. Terrett, of Tewkesbury, to be paid upon the death of his surviving sister. They have also been informed that another legacy of £300 has been left them by a gentleman now eighty years of age; and they hold out these examples to the imitation of their friends and supporters, reminding them that such legacies wholly go to the increase of their annuitants—a form of relief which as it is given to individuals to be enjoyed at home, in the domestic circle, and when once granted is inalienable, possesses peculiar claims to attention.

"At this part of their Report, the Committee beg to call your attention to the munificent gift of Mr. Bailey, of Chippenham, who has presented to your institution, and to individuals relieved from its funds, six houses, beautifully situated in that agreeable neighbourhood, abounding with every suitable convenience, and with the studied design of delicately considering the wounded feelings of the unfortunate of our profession.

"Mr. Bailey has also given to the trustees of the aforesaid cottages £500 in perpetuity, the income of which may be expended upon the necessary repairs of the said houses; and your Committee, while they feel quite unable to express their gratitude for these gifts, earnestly pray that the generous donor may be long spared to witness the success of his benevolent plans; and they hope to carry out all his views, with a religious attention to the wishes of their founder.

"Your Committee mournfully record the loss by death of one of their associates (Dr. Stilwell) during the year. He was present at one Committee, but before the next, had passed away from among their number. They would be stimulated by this fact, and by that other fact, "that they are all hastening to that country from whose bourn no traveller returns", to work while it is day, for the night cometh when no man can work; and they would urge this consideration upon all their subscribers and friends as a powerful motive to increase their subscriptions, and to augment their efforts in this cause of sacred misery. Death, too, has invaded in many instances the circle of their supporters; and in other cases the *res angusta domi*, a moral death, has abstracted much from your resources; to say nothing of that apathy which in some instances has deprived man of all his powers and privileges. Such considerations should induce all to exert a greater degree of providence, and a larger amount of self-denial, in order that, though circumstances may be strentened, the hand of charity, that bond of perfectness, may not be contracted.

"Your Committee refer to the following list of persons relieved during the year, and to the general sketch of appended cases, as to proofs of the energy and success with which your institution has been conducted, as well as to its indispensable necessity and importance:—

Physicians	-	-	-	-	-	5
Surgeons	-	-	-	-	-	20
Apothecaries	-	-	-	-	-	2
Wives or Widows of Physicians	-	-	-	-	-	2
Wives or Widows or Surgeons	-	-	-	-	-	19
Daughters of Physicians	-	-	-	-	-	2
Daughters of Surgeons	-	-	-	-	-	4
Families of the above, containing individuals numbering	-	-	-	-	-	283
Total	-	-	-	-	-	337

"It will be advisable in the course of next spring to hold the second biennial dinner of the Benevolent Fund, trusting thereby to augment the resources destined to granting annuities.

"During the past year, the conductors of the extinct British Medical Fund have transmitted a moiety of the balance left in their hands, viz., £11:14:0, which has of course been added to the Donation Fund.

"Several annuitants have died this year, but their places have been supplied by others; and your income during the year for this purpose, which is never exceeded, has been £110, whilst the amount invested in Bank Stock is now £1,600, which at the present quotations will produce £3680:6:0.

"The Committee have not been able to entertain the proposi-

tion of grafting a Sickness Relief Fund upon your institution, but they will zealously bestow their attention upon every legitimate proposition for diminishing the wants, or alleviating the sorrows of their unfortunate brethren.

"The number of cases aided during the year by casual grants or by annuities has been seventy-three, a proof that the wants of the profession have not diminished; and that your income has not been adequate to their relief. O suffer not this stain to be imprinted upon the pages of a future Report, but let it be clean washed away by the tear of pity, enlightened by the gilded ray of active benevolence.

"The amount of donations during the year has of course been less than in the preceding year, when the public dinner contributed so materially to your revenue; but it has been about the same as in the penultimate year, and the Committee hope for a large increase of this source of income during the next year, somewhat commensurate with their requirements, and with the extent of the evil they are called upon to relieve.

"To the renewed exertions of their lady friends, and the continued kindness of the medical press, to the uniform indulgence of their bankers, and to the unvaried kindness of their colleague, Mr. Churchill, in granting his rooms for the purposes of the Committee, as well as for the valuable services of their auditors, your Committee beg to express their deeply felt gratitude, as well as their request that they would continue their kind offices.

"And in conclusion, while entreating your support for the ensuing year, they would trustfully devote their aspirations of prayer and praise to Almighty God, that it would graciously please Him, the giver of all good, so to dispose the hearts of all towards your institution, that the abundance of their deep poverty may rejoice in the riches of your liberality.

"WILLIAM NEWNHAM, Chairman."

London, July 12th, 1853.

[We do not subjoin the list of cases relieved, as this would only be repeating our monthly reports of the proceedings of the committee who manage the Fund. EDITOR.]

Dr. CONOLLY, after passing a glowing eulogium on Mr. Newnham, moved the following resolution:

"That the Report now read be received and adopted; and that the cordial and heartfelt thanks of the Association are eminently due, and are hereby given, to Mr. Newnham, for his great and unwearied exertions in promoting the interests and increasing the amount of the Benevolent Fund; that he be requested to continue his valuable services as Honorary Treasurer and Secretary: and that the Committee be reappointed.

Dr. TUKE, of Chiswick, seconded the resolution.

THE PRESIDENT put the resolution, which was unanimously adopted.

Mr. NEWNHAM, in returning thanks to the meeting for the resolution, expressed his desire to devote to the Benevolent Fund the few and feeble years which might yet be granted to him by Providence. The Medical Benevolent College was not a rival institution: each had its own sphere of action; and he could not but regret deeply that any one should feel himself justified in discontinuing to subscribe to the Fund, because he had become a contributor to the College. The indispensable character of the Fund was evident from a single fact: viz. that of the seventy-three cases relieved by it during the past year, only one individual could have come within the scope of the College charity, supposing that that institution had been in operation. The College, he knew, had peculiar attractions to subscribers: it promised them patronage and education for their children; whereas the Fund offered no inducement to subscribe, except the luxury of doing good. He thought that the Fund Committee could not possibly avoid stating why they had lost subscribers. It was wrong that they should have lost them; but it was a fact; and a fact, moreover, which ought to be stated, and also explained. It grieved him (Mr. Newnham) very much to reflect upon the small number of members of the Association who had hitherto come forward as annual subscribers, or as donors to the Fund. Surely there was no member of the Association so poor as not to be able to contribute one guinea a year. It was not charity to give from our superfluities: true charity was given from the fruits of self-denial; and he was sure that, by the exercise of a little of this virtue, every one, or almost every one, might come forgard with his offering of a guinea. It was not creditable to the Association that its Benevolent Fund should be so inadequately supported.

Dr. CORMACK was inclined to differ materially from Mr. Newnham, as to the extent of the pecuniary ability of members to contribute. The total income of many members did not con-

sist of a very great number of guineas; and, when it was recollected that household and other expenses ought to have priority of payment over charitable donations, he (Dr. Cormack) was certain that a large deduction would have to be made from the number of members who could, or who ought, to subscribe a guinea annually to the Benevolent Fund. If members and their friends were invited to subscribe in sums varying from half a crown to a guinea and upwards, a larger sum would be realised than at present; as many now gave nothing, simply because they could not give a guinea. Small, as well as large donations ought, therefore, to be encouraged. Small amounts, in the aggregate, soon swell into a considerable total: and, by cultivating the humbler class of contributors, the benevolence of a much more extensive class of the community was enlisted, than could possibly be obtained in any other way. The chief weakness of the Fund lay, he (Dr. Cormack) thought, in a cause to which Mr. Newnham had not adverted, viz. the great error which had been committed of establishing a Committee, all the members of which, save one, resided in London. A centre of affairs was of course required: and London was the best centre, as it was the most accessible town in the kingdom. It had therefore been very naturally chosen; but the London trunk could not flourish and bear fruit unless the roots struck deeply down into the country, and unless it had auxiliary branches in every town. He was sure that if the Benevolent Fund had (like the Benevolent College) local secretaries and local committees, the annual subscriptions and donations would soon be more than quadrupled. The existing committee might carry out such a plan: and by enlisting the aid of the councils of the district branches of the Association, the basis of an effective machinery could soon be formed. He (Dr. Cormack) had ventured to make these suggestions to Mr. Newnham some time ago, and he was glad to think that they had been favourably received by that gentleman. The Benevolent Fund, like other departments of the Association, required a more representative organization to develop its vast latent power.

DR. OGLE, THE EX-PRESIDENT.

Sir CHARLES HASTINGS said, that those who had participated in the enjoyments of the meeting at Oxford last year, must be ready to concur in the propriety of the resolution which he was about to propose. They looked back with warm and grateful feelings to the splendid and hospitable reception which they had met with at Oxford: and they all felt how much they had been indebted to Dr. Ogle for his conduct during the year as their president. He therefore moved "That the thanks of the meeting be given to Dr. Ogle for his conduct as president during the past year, and that he be elected a Vice-President of the Association." [Cheers.]

Dr. CONOLLY seconded the motion, which was carried by acclamation.

Dr. OGLE, the vote having been announced to him by the Chairman, returned thanks. In doing so, he said that he could not but deplore his own deficiencies. [Cries of No, no.] He suffered from the infirmity of deafness, and he had thus been unable at all times to regulate the proceedings as he ought. He was grateful to those gentlemen who had yielded in the dispute as to the validity of the Journal decision; because, although he had explicitly stated his opinion, the question might easily have been made the source of protracted disagreeable feeling. Then, there was a passage in Mr. Hester's address, which, if he had heard when it was read, he would have noticed as out of place, and objectionable. It was not right, in his opinion, to make indirect attacks in the course of an address of an official character. If there is a charge against a man, let it be brought forward stripped of all ambiguities, and as an independent accusation. The accused is thus at once put fairly on his defence. He made this remark quite irrespective of the merits or demerits, the truth or the error of the charges contained in the passage of the Transactions to which he had alluded. He only meant to say that he regretted that, in his capacity of president of the meeting, he had not heard and objected to the passage, when it was read, as being out of place. As the subject was to be brought formally before the meeting, he would read a letter which he had received from Mr. Hester.

MR. SYME AND MR. HESTER.

Sir CHARLES HASTINGS, in reference to the remarks of Dr. Ogle, said, that Mr. Syme had become a member of the Association in January; and had very soon afterwards resigned in consequence of a passage contained in Mr. Hester's Address in Surgery, delivered last year at Oxford, and published in the recently issued volume of Transactions. Mr. Syme was no longer a member of the Association; but the subject had been brought before the Worcester Council by a gentle-

man eminent in his profession and an old member of the Association; he referred to Dr. Simpson, Mr. Syme's colleague. He was sorry to say that Dr. Simpson's letters were written in a very angry spirit. He had explained to Dr. Simpson that the question was one in which the Worcester Council could not interfere in their official capacity, as they had no right to sit in judgment upon an address for which the author had received the thanks of an anniversary meeting, and which, by the same meeting, had been ordered to be printed in the *Transactions*. He, in common with everybody else, regretted that such a passage had been published under the sanction of the Association; but he equally regretted that, in place of allowing time for friendly negotiation, Mr. Syme had, on perusing it, tendered his resignation so hastily, and so passionately, as to throw difficulties in the way. The Worcester Council could not interfere; and it was now his duty, as President of the General Council, to bring the subject before this meeting; and he hoped that it would be dealt with in such a way as would satisfy their friends in Edinburgh that the Association did not hold itself responsible for everything which appeared in an address ordered to be printed upon the ground of general merit.

Dr. OGLE was not going to enter into the details of this unpleasant dispute. When on the platform of the station at Oxford, about to start for Swansea, Mr. Hester had placed a long letter in his hands upon this subject, in which he expressed his regret at being unable to attend the meeting, and in which he likewise, in very proper terms, placed himself entirely in the hands of his fellow associates. [Dr. Ogle read the letter, which was a very long one. The object of Mr. Hester was to show that it was from a sense of public duty, and not from the slightest personal feeling, that he had condemned eminent surgeons resorting to courts of law to settle their squabbles.]

Some conversation took place among members, chiefly as to whether the subject was one which could be entertained by the meeting.

Dr. CORMACK then rose, and said that he agreed with everything which Sir Charles Hastings had said. It would be a most dangerous course for the Association to adopt every sentiment of every paper which was printed by its authority. This was not done by the Royal Society, or by the Royal Medical and Chirurgical Society; and why should it be done by the Association? As some had said—without any reasonable grounds, he admitted—that the Association had formally censured Mr. Syme, Mr. Lizars, and the whole profession in Edinburgh, by sanctioning Mr. Hester's address, it seemed expedient to pass such a resolution as would effectually silence such a statement, and prevent the possibility of the recurrence of any similar case. Mr. Hester was mistaken when he spoke of two "leading surgeons having appealed to a court of law upon a question of truth"; for Mr. Syme had simply been the successful defender in an action for libel, and the alleged libel was actually a defence from an attack by Mr. Lizars. He (Dr. Cormack) was sure that Mr. Hester, or any gentleman, having had this pointed out to him in a conciliatory manner, would have withdrawn the erroneous statement; but he believed that Mr. Syme's letter of resignation was the first intimation which Mr. Hester received of Mr. Syme's displeasure. This abrupt conduct on the part of Mr. Syme was not calculated to obtain for him their sympathy; but, nevertheless, it must not be allowed to operate in such a way as to prevent the Association from doing an act of justice to itself by passing such a resolution as he was about to propose. Before doing so, he would read the passage in Mr. Hester's address which had called forth this discussion:

"If we cast our eyes beyond the Tweed, we see the melancholy exhibition of a city, celebrated through long ages as the birthplace of genius, torn by two rival factions, and a petty squabble about the perineal section. It is not in these days a question whether the operation originated with Dessault or Syme, nor whether it be adapted for the cases in which it has been recommended. The ultimate condition of the patient is lost sight of in fierce animosity and personal invective; and the two leading surgeons have appealed to a court of law upon a question of truth. *Proh pudor!* It were vain to expect them to issue from the contest humbler, better, and wiser men. But should their repentance be ever so great, it will never efface the scandal such proceedings bring upon the profession."

The following resolution was then proposed by Dr. CORMACK, who stated that it was one which had, on the motion of Mr. Norman of Bath and after considerable discussion, been unanimously adopted by the Council on the previous evening as a suitable one to submit to the general meeting.

"That this Association regrets that there should be any misunderstanding between Mr. Syme and Mr. Hester relative to

the retrospective address on surgery; but that this misunderstanding is a subject in which the Association cannot interfere, inasmuch as it does not hold itself responsible for all the sentiments expressed in the papers which may be published in the *Transactions* of the Association, or recommended for publication on account of their general merits."

Dr. HENRY seconded the resolution.

Dr. SIBSON rose to offer an amendment, because he felt that the resolution proposed might be considered as a censure upon Mr. Hester; and he was not prepared to concur in any resolution which admitted of such a construction. He said this without at all giving an opinion upon the passage which Dr. Cormack had read; and most fully agreeing with that gentleman (Dr. Cormack) in thinking that the Association was not responsible for all the sentiments expressed in papers published under its authority. The letter to which he referred was not worthy of a man who occupied so high and so influential a position in the profession as Mr. Syme; and it had been very properly refused a place in the *Medical Gazette*. He (Dr. Sibson) could not give his vote in favour of any motion the tendency of which was to exonerate Mr. Syme and to blame Mr. Hester. Mr. Hester had placed himself in the hands of the meeting; but that was no reason why they should respond to Dr. Simpson's appeal by censuring Mr. Hester. He thought that the resolution ought to be expressed in the most general terms which could be found. He therefore proposed this amendment.

"That the Association regrets that there should be any misunderstanding between Mr. Syme and Mr. Hester; but that the Association does not hold itself responsible for the sentiments expressed in the papers which may be published in the *Transactions*, and recommended for publication on account of their general merits."

Dr. CORMACK: I see no difference between the amendment and the resolution.

Dr. SIBSON: Then will you withdraw the resolution in favour of the amendment?

Dr. CORMACK: No; because the resolution has already been unanimously adopted by the General Council.

Mr. HANSARD, of Oxford, as the friend and colleague of Mr. Hester, had no objection to the original motion. To express regret at a misunderstanding was not to fix an opprobrium upon the parties; he could not see how Dr. Sibson regarded the expression of regret as a censure upon Mr. Hester and not upon Mr. Syme. Both were spoken of in the same phrase; and neither was censured by it.

Dr. OGLE regretted the language which Mr. Hester had used; and Mr. Hester regretted that he had used it, as it had occasioned annoyance to others. He (Mr. Hester) had not withdrawn it, merely because he had received no information to lead him to doubt the correctness of his statements. Dr. Ogle did not perceive any censure upon Mr. Hester or Mr. Syme either in the motion or in the amendment.

Dr. RADFORD, of Manchester, concurred with Dr. Sibson, and seconded the amendment.

A desultory conversation ensued, in which some thought that there was a difference between the original motion and the amendment, and others maintained an opposite opinion.

Dr. CORMACK, in reply, said that he would not withdraw the resolution in favour of the amendment, because he did not see its superiority, and observed only a trifling difference in its phraseology.

The PRESIDENT then put the amendment, which was carried by 29 against 18. The original motion was then put, and lost; the numbers being the same as in the previous division. Sir C. Hastings, Dr. Ogle, Mr. Hansard, and others, did not vote.

ADDRESS IN SURGERY.

The Address in Surgery was read by AUGUSTIN PRICHARD, Esq., of Bristol.

Mr. NORMAN moved—

"That the cordial thanks of this meeting be given to Augustin Prichard, Esq., for his able and interesting address; and that he be requested to allow the same to be printed."

Mr. PAGET, of Leicester, seconded the resolution.

The PRESIDENT put the resolution, which was carried unanimously.

THANKS TO COUNCIL: REAPPOINTMENT WITH NEW MEMBERS.

It was moved by E. Y. STEELE, Esq., of Abergavenny:—

"That the thanks of the meeting be given to the Council of the Association, for their services during the past year; and that they be requested to continue the same, with the following additional members:

"Augustus Eves, M.D. (Cheltenham); Edward Ingram, Esq. (Boston, Lincolnshire); David Everett, Esq. (Worcester); R. H. McKeand, Esq. (Manchester); Thomas Mellor, Esq. (Manchester); John Robertson, Esq. (Manchester); William Smith, Esq. (Manchester); Sir James Lomax Bardsley, M.D. (Manchester); M. Eason Wilkinson, M.D. (Manchester); James Whitehead, M.D. (Manchester); Edmund Lyon, M.D. (Manchester); William Rowland, Esq. (Swansea)."

Dr. NICOL, of Swansea, seconded the resolution, which was carried unanimously.

REPORT OF AUDITORS.

The Auditors, Drs. TUNSTALL and LINGEN, reported that they had examined the accounts of the Association, and compared them with the vouchers, and that they found them perfectly satisfactory.

CONVERSAZIONE IN THE NATIONAL SCHOOL ROOMS.

In accordance with previous announcement, the President and members of the Monmouthshire and South Wales Branch, and the Local Committee, received the members of the Association, and many gentlemen of the town and neighbourhood, in the National School Rooms, at eight p.m. There was a large attendance, resembling very much the memorable meeting of the British Association at Swansea in 1848. In addition to the various members of the medical profession, we observed—J. J. Strick, Esq., Mayor of Swansea; J. H. Vivian, Esq., M.P.; Graham Vivian, Esq.; Admiral Warde; P. St. Leger Grenfell, Esq.; T. Edw. Thomas, Esq.; M. Moggridge, Esq.; J. Biddulph, Esq.; Rev. E. B. Squire, Vicar of Swansea; Rev. S. Davies (Rural Dean); Rev. T. S. Hughes; Rev. W. Thomas; Dr. Noon; Rev. Thomas Thomas, Pontypool College; W. Chambers, Llanelly House, Esq., etc. etc.

The appearance of the room excited general admiration. It was brilliantly lighted with gas, and most beautifully fitted up, under the superintendence of Mr. W. H. Michael, the District Secretary of the Association, on whom too much praise cannot be bestowed, for the taste and judgment displayed in the selection and arrangement of the products of the Welsh mountains, the *chefs d'œuvre* of native artists, and the floral beauties of the neighbouring gardens. The walls were hung with

"Pictures for the eye",

whilst the various tables were plentifully covered with

— "Exquisite and costly things,
Each sense to gratify."

The pictures, we understand, were procured and arranged by Mr. W. Palmer, of Wind-street, to whom much credit is due. A most agreeable and refreshing effect was produced by two water fountains (fitted up by Mr. Arnold, of Temple-street, Swansea) near the centre of the room, which played in the midst of rock work and water plants.

Many of the tables were highly interesting: that appropriated to the Ystalyfera Iron Works was especially so, from its containing very fine specimens, showing the results of the various processes in the manufacture of iron. The fourth of a plate of fine silver from the Landore New Silver Works, was an object of great attraction. It weighed about 150 lbs., and is estimated as being worth about £800. Mr. Michael Williams's Ynismudw Pottery ware, terra cotta wine coolers, and exterior architectural decorations, were very fine specimens, and were minutely inspected.

Mr. Hennessey, of Wind-street, Swansea, lent for the occasion some of his new "Model Barometers", exhibited to show at what a low price a highly efficient instrument may be supplied. He also exhibited the sympeirometer, which is much used at sea, from being more sensitive than the mercurial barometer: it is equally applicable for land purposes. Mr. H. likewise sent in his fine model of the "Koh-i-Noor" diamond, made from the stone known as the Cornish diamond, sometimes found in the copper mines of Cornwall. Specimens of malachite, both in the rough as well as cut and polished, ready for the jeweller's mounting, were shown. These elegant articles of jewellery attracted the attention of many; especially as they have a sort of local interest attached to them, being manufactured from the malachite imported from the Burra Burra mines of Australia, to be smelted at the extensive works in the neighbourhood of Swansea. This completed Mr. Hennessey's collection.

Mr. Gale, of Wind-street, Swansea, contributed some of his useful articles, showing the practical and varied uses to which gutta percha can be applied in the present day.

There was a large assortment of medical and surgical instruments, microscopes, etc. Mr. Weiss, of London, lent for the occasion a very interesting collection of instruments.

The staple manufactures of the neighbourhood were illustrated by many beautiful series of specimens. The manufactures of

copper, iron, tin, and silver, were represented by complete series, from the rude ore to the refined metal, variously suited for different purposes. There were specimens of all the kinds of coal, and the fossils of the coal formation of South Wales. The pottery manufactures were illustrated in a direct line from the raw clay to the most ornamental designs in delf and crockery ware; with specimens of porous ware, for useful and ornamental purposes, from the clay found in the coal strata; also, pipe-tiles, crests, pillars, fire bricks, and a variety of articles demonstrating a very important manufacture of the district. We likewise observed fine selections of all the minerals either found or used in the neighbourhood, and all the chemicals manufactured. Most interesting specimens were shewn of all the various descriptions of rails used on every road in the world; as well as iron in every variety, from its ornamental use to its forming a book no thicker than ordinary paper.

The plants and flowers, with which the rooms were decorated, comprised some of the rarest and most beautiful of the vegetable treasures of the tropics—the palm, the coffee plant, the chocolate plant, ornamental flowers, etc.

The company separated about eleven o'clock, highly delighted with the hospitality of their reception, and the greatness of the intellectual treat which had been prepared for them.

[Our report of the conversazione is nearly a reprint from *The Cambrian*, a Swansea newspaper.]

THURSDAY.

At half-past eight o'clock there was a public breakfast at the "Mackworth Arms", which was attended by about one hundred and fifty gentlemen. The President presided. He announced that the beautiful grounds of Singleton Abbey, as well as the various manufactories of the neighbourhood, were, by the kind permission of their respective proprietors, open for the inspection of the members of the Association. Many availed themselves of these opportunities. The provincial physicians occupied the time between the breakfast and the assembling of the Association at twelve o'clock, by attending a meeting, which we have reported in another page.

ADDRESS IN MEDICINE. BY DR. C. RADCLYFFE HALL.

The Address in Medicine was delivered by Dr. C. RADCLYFFE HALL, of Torquay. The subject was, "Nature's Modes of Arresting Tubercular Disease of the Lungs". [We regret that from the great extent, as well as the abstruse nature of this talented discourse, we cannot at present give an account of it without doing injustice to the author.]

Dr. TUNSTALL had sincere delight in moving—

"That the hearty and best thanks of this meeting be given to Dr. Charles Radclyffe Hall for his instructive and talented address; and that he be requested to allow the same to be printed."

Dr. THOMAS WILLIAMS, of Swansea, seconded the resolution; and in doing so, complimented the author upon having given a clear exposition of one of the most abstruse questions in medicine.

The PRESIDENT put the resolution; which was unanimously carried amid much applause.

MEETING NEXT YEAR AT MANCHESTER.

SIR CHARLES HASTINGS said that it was well known that there was a strong and a general feeling in favour of the next anniversary of the Association being held at Manchester. It was not necessary that he should remind the meeting of the many and the extraordinary circumstances which combined to give power and distinction to Manchester. It was the capital of one of the most important sections of the kingdom; and from all points the access to it was easy. Having received an influential requisition from the profession in Manchester to hold the next anniversary in that town, he thought that the Association ought to do so. (Cheers.) He would, however, be wanting in courtesy to the profession in Harrogate, if he did not state that they had likewise forwarded a requisition of the same kind as that which had been received from Manchester. It was most numerously and influentially signed; and in the absence of the Manchester requisition, would have been complied with. In all the circumstances, however, he was sure that their friends in Harrogate would not feel that there was any discourtesy in his proposing

"That the anniversary meeting for 1854 be held at Manchester; and that W. J. Wilson, Esq., be appointed President-elect." [Cheers.]

Mr. SODEN said that seventeen years ago the Association had held a most successful and agreeable anniversary at Man-

chester. He had therefore much pleasure in seconding the resolution.

The PRESIDENT put the resolution; which was carried unanimously.

ADDRESSES IN MEDICINE AND MIDWIFERY FOR NEXT YEAR.

Mr. NORMAN said that it had been usual to appoint gentlemen to deliver addresses in medicine and surgery at their annual meetings; but hitherto the important subject of midwifery had been neglected. It was now thought that, for next year, the address in surgery ought to give place to an address in midwifery. (Hear, hear.) He therefore proposed

"That Dr. Radford, of Manchester, be appointed to deliver an address in midwifery at the anniversary meeting of the Association in 1854."

The PRESIDENT put the motion; which was carried unanimously.

Dr. RADFORD highly appreciated the compliment which had been paid to him; but he also realised the difficulties of the proposed duty. He would, however, undertake it, by selecting some important and interesting subject in midwifery, and doing his best with it.

Dr. COWAN moved

"That Dr. Conolly be appointed to deliver the address in medicine at the anniversary meeting of the Association in 1854."

Dr. SIBSON seconded this resolution.

The PRESIDENT put the motion; which was carried unanimously.

Dr. CONOLLY feared that for the last fifteen years he had not kept up with all the departments of medicine; and that in fact he had become a man of one idea—or at least a man who was occupied with one pursuit in medical science. As, however, the example had been so ably set by Dr. Hall, of selecting a single subject for discussion, he was less reluctant to accept the duty of giving the address at the next anniversary. If he listened only to the voice of prudence, he ought, as he well knew, to beg to be excused. Manchester was, however, connected with his early attachment to the Association, to which he had through many years entertained a most faithful affection—an affection which could only end with his days. Under these circumstances, he was unwilling to decline the proposed honour. (Cheers.)

CLIMATE AND VITAL STATISTICS OF BATH. BY DR. TUNSTALL.

Dr. Tunstall, from the want of time, was only able to give a sketch of an able and elaborate work on this subject.

ORDER OF PROCEEDINGS.

Dr. WILLIAMS having been called on by the President, Dr. CORMACK requested permission to ask a question.

SIR CHARLES HASTINGS: Dr. Williams has now the right to be heard. To stop the proceedings in this way is most inconvenient. It is most important that the remaining business be got on with as rapidly as possible. I am very sorry to call Dr. Cormack to order; but I am sure he will see that I am right.

Dr. CORMACK: I can ask my question in a sentence; and the President can answer it by a monosyllable. I ask: Is Mr. Michael's motion on Medical Ethics to be discussed to-day?

Dr. MORRIS, of Chepstow: I was about to have asked the same question.

Mr. W. H. MICHAEL: I am here at great personal inconvenience; and it is—

SIR CHARLES HASTINGS: I knew how it would be. If the order of the programme be not adhered to, all our time will be consumed in doing nothing.

The PRESIDENT: Dr. Williams, you had better proceed.

ORIGIN, TRANSFORMATIONS, AND DECLINE OF THE FLOATING CELLS OF THE BLOOD. BY THOMAS WILLIAMS, M.D.

Dr. WILLIAMS illustrated his subject by many instructive diagrams. As a brief abstract would be of little use, we must postpone our account of this valuable paper.

ULTIMATE STRUCTURE OF THE AIR-CELLS CONSIDERED IN ITS RELATION TO CERTAIN OF THEIR DISEASES. BY THOMAS WILLIAMS, M.D.

This communication consisted of a brief explanation of drawings and diagrams.

ORDER OF PROCEEDINGS.

The PRESIDENT: Dr. Sibson's communication comes next on the programme.

Mr. W. H. MICHAEL: It is now nearly half-past three o'clock, and at great inconvenience I have been waiting all day to be called on to bring forward my motion on Medical Ethics.

The order of business as communicated to me by the secretary has been departed from. I wish to know why this has been done, and by whose authority it has been done? I shall divide the meeting as to my right to have these questions answered. [Cheers.]

The PRESIDENT: I shall be very happy to take the sense of the meeting upon any proposition which Mr. Michael may wish me to put. At the same time I assure Mr. Michael that I have strictly followed the order of proceedings as placed in my hands by the Secretary.

The SECRETARY (Mr. SHEPPARD): The statement from the chair is quite correct: but in justice to Mr. Michael I must say that I did inform him (Mr. Michael) that his motion would come on immediately after Dr. R. Hall's Address in Medicine. It was put down in the paper for yesterday afternoon; and as it was the first of those motions which were left over from yesterday, I thought that it would be taken to-day as the first thing after the Address.

Mr. MICHAEL had, within the last five minutes, seen, for the first time, the programme of business. He had never heard till now that his motion was set down for yesterday afternoon; and if he had been then called upon, he could not have responded, as he was engaged in concluding some necessary arrangements connected with the conversazione. He did not know by whom the order of business was fixed: but he thought the present plan most objectionable. Nobody knew what was about to be taken, till the subject was announced by the President, for immediate consideration. In place of one copy of the programme lying before the President, a list of the order of business ought to have been posted at the entrance to the building, in the lobbies, and in the hall of meeting, so that every member might know when the subjects in which he was interested were to be brought forward. He had months ago given notice of his motion: it stood first in the printed programme of business published weeks ago in the Journal, and he must say that he had good reason to complain of having his right of priority thus invaded—his right of priority, he said, because it had been officially announced by the Secretary that motions were to be taken in the order in which they had been intimated to the Secretary. He maintained that the proper order of business had been departed from: wherefore, and by whose authority, he knew not. To prevent such irregularities occurring again, he should move, if at Manchester next year, that a special committee be appointed to arrange the business during the reading of the report of the council, and be prepared to report at an early stage of the proceedings, so that printed lists might be at once prepared and circulated. [Cheers.] He wished this to be taken as a twelve-months' and formal notice of his intention. In the meantime he maintained that he ought, without further loss of time, to be allowed to proceed with his motion. [Go on, and cheers.]

The PRESIDENT said, he thought Mr. Michael was sufficiently well acquainted with him to know that he wished to be strictly impartial. As to the arrangements, which had been made with the secretary, he (the President) was in perfect ignorance till this discussion arose. He had followed the order of proceedings which had been placed in his hands. It must be perfectly obvious to every gentleman present that it could be no object to him in what order the business was taken. For his own part, he should be glad if it was the pleasure of the meeting that the important question of medical ethics should now be discussed.

Sir CHARLES HASTINGS would be sorry if Mr. Michael supposed that he (Sir Charles) had any other wish than to save time in recommending adherence to the appointed programme.

The PRESIDENT had abided by the programme which had been read to him: but from the explanations which had taken place, he thought that it would be desirable to allow Mr. Michael at once to proceed with his motion. [Cheers.]

MEDICAL ETHICS.

Mr. W. H. MICHAEL said, that at that advanced hour, and with several other subjects to be attended to before the meeting separated, he would detain them only for a very short time. Had he been aware, when he gave notice of his motion, that an Ethical Committee of the Association had been appointed three years ago, and was still in existence, he, probably, would not have taken that step; but as the Committee had not been able to agree upon any report, he did not now feel inclined to draw back. It might assist the labours of the old committee to alter its constitution, or infuse into it new blood. The ethical question was one which vitally affected the interests of the Association, and was one which conduced to exert a greater influence upon the profession than even the legislative enactments for medical

reform which the Association now sought. It was in their hands to influence, not only their own body and profession, but also, by union and acting in concert, in a great measure to influence the public and the legislature; and they only lost that power and that influence when they departed from the bonds of union which should regulate their conduct. [Cheers.] They were at present a great Association, all aiming at one common object and endeavouring to promote the same end; and it would therefore be evident to every gentleman that when they had to contend with great and serious difficulties they should be united,—and it was in consequence of not having proper rules for the guidance of their body that so much of disunion, of difference and of jealousy existed at present. [Hear.] The true view of the medical profession was that of a body of men contending against a giant evil; and by union, and mutual support, waging war against sickness, disease, and death—admitting no intestine feud, and allowing no jealousy of superior merit to interfere with their holy mission, which was the relief of suffering, and the alleviation of distress. To promote this union, to aid in this warfare, must be the object of any code of ethical laws; to bind closer together brethren striving for the common good and well-being of suffering humanity. [Cheers.] To them the amelioration must be from within more than from without, for he had more confidence in the help from internal concord, than from external assistance.

He (Mr. Michael) had received letters maintaining that it was not desirable that the Association should have a code of ethical laws; as they would only be the means of creating and spreading discord. But he did think that gentlemen who were of that opinion could have but a very imperfect idea of the true objects of medical ethics. For what was meant by ethics? it was a subject comprised in the motto "*Ars bene vivendi*". It was merely placing upon paper those rules which guided, or should guide them in the every day occurrences of life. It was but converting the *lex non scripta* into the *lex scripta* of the medical profession. How often was it requisite that they should have a code of rules for the guidance of their body, in the many circumstances which arose in their relations to the public, which would make it proper that they should fall back upon these rules, and would enable the public to understand the reason of their action? He would not now allude to any illustrations, because the facts to which he referred must be familiar to every member of the Association. It must therefore be evident that by having a well-digested code of rules drawn up for the guidance of the members of the Association, they had thereby given them the opportunity of avoiding personalities, and being aided in those trying circumstances which so often occurred in the intercourse of the public with the profession. He did not mean to say that, by their having a certain code of rules drawn up, it would make every member act on all occasions as a gentleman; but he did believe it would be the means of doing much good, and would enable them to place in a much better position than he now occupied the hard-worked and ill-paid union surgeon, "passing rich on £30 per year." [Laughter.] Boards of guardians could now feel perfectly indifferent when the resignation of a surgeon was sent in; and the reason of that was, they well knew that the medical profession was so disunited and divided, that they would be secure in calculating on many applications for this situation, with its enormous salary of £30. [Laughter.] But, whilst he thought it was highly desirable, and even necessary, that they should have rules for their guidance, he believed that, after all, upon each member must chiefly depend the duty of elevating the profession. If every individual member would strive by every means in his power, strictly in accordance with the laws of right and truth, to advance the interests of the profession, it would be seen that their object was not merely their own self-aggrandisement, but the interest of the public at large; and he believed that, as a body, they would be more highly estimated by the public. They would perhaps meet with many obstacles, which would have a tendency to cripple their efforts; but, at the same time, if they set about the matter in the right spirit, success was certain. The Association possessed within itself a potent influence for good; but it likewise had a power which could be diverted to evil.

As at present constituted, the membership of the Association afforded no guarantee of honorable conduct; for its wide portals admitted all, without inquiry, upon the recommendation of two members. To effect the main object of the Association, the elevation of the status of the medical profession, this laxity must be in future avoided. He wished to have it considered as a high honour to be a member of their Association. He would make it an assurance of moral integrity, and a guarantee of honorable action in all the varying and trying scenes of profes-

sional live. How true in the profession is the maxim—"Aide toi et Dieu t'aidera"! Union here is indeed strength; for by it are attained increased knowledge, and improved means for its acquisition; power to grapple with disease in its varying forms, and assistance to combat with distress in its direst and worst forms. To be united, is to show the public how much they are indebted to us as a profession; and to obtain from them a better opinion, and a more just remuneration. By clearly stating the laws for their governance, and by an adherence to those laws, he could not but believe that the Provincial Association, the profession, and the public, would be equally benefited. He would not further detain the meeting, because the appointment of a committee for this purpose, on a previous occasion, proved that the Association had estimated its importance, and had admitted the truth of the general principle which he had endeavoured to advocate. He should therefore move

"That a Committee, consisting of Dr. Cowan, Dr. Sibson, Dr. Cormack, [and four others, whose names we lost,] along with the Secretaries of the District branches, be appointed to frame a code of ethical laws for the Association; and to report to the next anniversary meeting." [Applause.]

Sir CHARLES HASTINGS said that it would be an ungracious act not to reappoint the existing Committee, which consisted of Dr. Conolly, Dr. Greenhill, and Mr. Flint. He had lately received letters from two members of the Committee, in which they expressed regret at their inability to report, and to be present at this meeting. He thought that it would be much better to wait for the report of the Committee which had already been appointed. For his own part, without disparaging the new Committee which had been proposed, he had more confidence in the old Committee, who had already given their attention to the subject, and discovered its difficulties.

Dr. CONOLLY believed that the existing Committee had suspended their labours, from the great difficulties which they had to contend with, in fixing the limits of the subject with which they had to deal. For his own part, he thought that the way to promote sound ethics within the Association, was for each individual to look to his own conduct. When he saw that in their body there were individuals of the very highest character—men with whom it was an honour to associate—and that there were likewise others of a very different description, he felt that very great difficulty must be experienced in drawing up a suitable code of rules for the guidance of their conduct to each other and the public. Glad should he be to entertain hopes as sanguine as those of his friend Mr. Michael; but he feared that Mr. Michael's hopes would pass like a dream, and never be realised. He had no wish to throw any obstacle in the way of Mr. Michael's resolution; and he was sure that the absent members of Committee would be equally unwilling to do so. He only feared that the good results which were anticipated would never be obtained.

Sir CHARLES HASTINGS suggested to Mr. Michael, that it would be better to reappoint the old Committee, with the addition of two or three new names.

Mr. W. H. MICHAEL had no objection to include the old Committee in the new; but he thought that, as the old Committee had never been able to agree to any report, no progress was likely to be made with the inquiry, unless a considerable number of new members were added. He had no objection, with the permission of the meeting, to modify his resolution as follows:

"That the Medico-Ethical Committee be reappointed, with the addition of the Secretaries of the District Branches—any five to be a quorum; and that they do report to the next anniversary meeting of the Association."

A desultory conversation followed, which was terminated by Dr. TUNSTALL moving as an amendment:

"That the consideration of the subject of Medical Ethics be deferred."

He said that, although the subject was important, no injury, but good, would result from delay. When the College of Physicians got its new charter, they would issue new bye-laws, which would be useful to guide the profession in forming ethical laws: and as at Manchester there was a Medico-Ethical Society, they might with great advantage defer the consideration of this subject till they met at Manchester next year. If anything was now done, it ought to be the reappointment of the Committee, with the addition of a few names, as suggested by Sir Charles Hastings.

Dr. Sibson hoped that Mr. Michael would be satisfied with adding a few names to the old Committee. Dr. Tunstall's amendment might not then be necessary.

Mr. SODEN thought that, considering the difficulty of the subject—the task of framing rules for the guidance of a large and diversified body—a little more time ought to be allowed to the Committee before they were superseded. He knew that Mr. Flint had given much attention to the subject; and a valuable report, he thought, might ere long be expected from the present Committee.

Dr. CORMACK differed very much from those who considered that the postponement of this subject from year to year was a matter of indifference. If the Association was to go on in a career of prosperity, it must aim at increasing its respectability as well as its numbers. Its rights of membership must be given only to honourable men; and membership must be made a certificate of professional propriety. [Hear, hear.]

Sir CHARLES HASTINGS doubted whether any system of admitting members could be adopted better than that which had hitherto been adopted.

Dr. WILLIAMS seconded Dr. Tunstall's amendment.

Mr. W. H. MICHAEL replied. He still thought that it would be wrong to delay another year; and, as regarded what had been said of Manchester, he would remind them that it was only by preferring his resolution to the amendment that a code of medical ethics could be prepared for discussion at Manchester. The Committee, as proposed in his amended resolution, was perhaps the best which could be devised. It contained the experience of the former Committee; and, by adding only the district secretaries, all idea of partial selection was got rid of, as the secretaries were named in compliment to their official position, and not from their individual qualifications. He believed that the district secretaries possessed an amount of knowledge of the state of the profession within their bounds which would be found to be materially useful. They would also be able to collect in each locality the general sentiments of members.

The PRESIDENT put the amendment, when the votes stood thus:

For the amendment,	. . . 10
Against it,	. . . 27

Majority against amendment, 17

The resolution was then put, when the votes stood thus:

For the resolution,	. . . 27
Against it,	. . . 16

Majority for resolution, 11

Dr. Conolly and others did not vote on either division.

[The votes were counted several times before everybody was fully satisfied. As this confusion when a division occurs frequently happens, it might not be amiss to adopt some more satisfactory and uniform method than any of those now usually adopted. It was suggested that each associate, when he voted, should stand up, and that his name should be announced and taken down by the secretary. This plan would certainly secure accuracy; but there are other plans which might be adopted.]

The PRESIDENT said that as the question had now been decided, he might be allowed to say that he hoped that the labours of the Committee might result in the formation of a good code of ethical rules. He trusted that members would always pay due respect and deference to the opinions of that eminent individual who had been mainly instrumental in founding the Association, and who had so long and so well managed its affairs. [Hear, hear.]

Mr. W. H. MICHAEL said that he hoped no one would for a moment entertain the idea that he had said or done anything which was either intended or could possibly be construed into disrespect for the founder of the Association. [No, no.]

MEDICAL BENEVOLENT COLLEGE.

Dr. COWAN moved

"That as the Provincial Medical and Surgical Association is established to promote, among other objects, the social improvement of the profession, this meeting hails with infinite satisfaction the establishment of the Medical Benevolent College—an institution which is intended for the benefit of the medical profession throughout England and Wales, and which will confer inestimable blessings by relieving the distress that exists among many deserving members, and the widows of those deceased by affording also to the sons and orphans a collegiate education, whereby they will be qualified to fill any situation in life."

Dr. CONOLLY seconded the resolution.

The PRESIDENT put the resolution; which was carried by acclamation.

CONSTITUTION, LAWS, AND FINANCES OF THE ASSOCIATION.

Dr. CORMACK believed, in common with many others, that the laws of the Association required to be consolidated, revised, and made more catholic: and also that a definite system of finance, embracing the formation of a sinking fund, was a desideratum. Deeply impressed with the urgency and importance of these questions, he had given notice of certain resolutions bearing upon them. He had no pet scheme to promulgate; and his only object was to obtain the appointment of an impartial committee to consider these subjects, as he thought that better results were likely to arise from the deliberations of such a body than from the vote of an unprepared general meeting. He also had thought that if the differences of opinion which prevailed on the subjects to which he referred were to be made topics of unrestrained discussion in the Journal, much valuable space would be wasted without any good being accomplished. He would not, however, at so late an hour bring forward his resolutions. It would be impossible to do justice to the subject. He therefore withdrew the resolutions of which he had given notice at p. 533 of the Journal of June 24th, in the hope that the objects which he had alluded to would not be lost sight of.

MEDICAL ANATOMY IN RELATION TO DIAGNOSIS. BY DR. SIBSON.

Dr. SIBSON made a short and very interesting communication, which he illustrated by diagrams.

DR. SIBSON'S SPRING PLEXIMETER. BY DR. SIBSON.

Dr. Sibson exhibited his pleximeter, which consists of a combination of Piorry's ivory pleximeter, and the hammer of Dr. Winterich introduced into this country by Dr. Hughes Bennett.

The hammer strikes upon the piece of ivory by means of a spring. Dr. Sibson prefers the fingers as a general rule, with or without the aid of Piorry's pleximeter, to any other mode of percussion. It is, however, sometimes impossible to percuss with the fingers with equal force on the two opposite sides, as for instance, in the axillæ. In such instances, Dr. Sibson's spring pleximeter may often be used with advantage, since the successive strokes are exactly equal, and ought to elicit, under similar circumstances, exactly the same sound. Another advantage possessed by the instrument is the ease and precision with which it can be applied over the clothes. In this respect it is particularly suitable in percussing children and females, and males during the cursory examination for life assurance.*

BED FOR DIRTY LUNATICS. BY DR. DAVEY.

Dr. CONOLLY, on behalf of Dr. DAVEY, of Northwoods, Bristol, exhibited the model and drawings of a bed for the use of dirty patients.

POCKET MICROSCOPE. BY DR. DAY.

Dr. DAY exhibited a pocket microscope, which he stated that he had found very useful while visiting patients. In reply to a question from Sir Charles Hastings, Dr. Day said that the instrument could be obtained from Pillischer, of New Bond Street, London.

THANKS TO AUTHORS.

Dr. HOWELL, of Swansea, moved

"That the thanks of the Association be given to those gentlemen who have read cases, and made communications to the meeting."

Dr. NICOL, of Swansea, seconded the resolution; which was put by the President, and unanimously carried.

THANKS TO THE MAYOR OF SWANSEA.

Dr. DAY moved

"That the thanks of the Association be given to the Worshipful the Mayor of Swansea, for his kindness in granting the use of the Guildhall on this occasion."

Mr. SODEN seconded the resolution; which was put by the President, and unanimously carried.

THANKS TO THE PRESIDENT.

Dr. TUNSTALL proposed

"That the thanks of the meeting be given to Dr. Bird for the very kind manner in which he has received the Association; and for his able conduct in the chair."

Dr. RADFORD seconded the resolution; which was put by the President, and unanimously carried amid much applause.

The PRESIDENT said that he felt exceedingly obliged—deeply obliged—for the vote of thanks which they had accorded to him. He assured them that he was proud and happy to receive such a vote of thanks from his professional brethren. With respect to his conduct in the chair, he wished that it had been better. He had, however, done his best, and he was grateful for their kind acknowledgments. To each and all of them he tendered his grateful thanks, most cordially wishing them health, happiness, and prosperity. [Loud cheers.]

The meeting then broke up a few minutes past six o'clock.

THE DINNER.

At seven o'clock, a party of above a hundred of the members and friends of the Association sat down to dinner in the Assembly Rooms. Dr. Bird (President of the Association), occupied the chair, supported on the right by J. H. Vivian, Esq., M.P., R. H. Miers, Esq. (High Sheriff of the County), J. J. Strick, Esq. (Mayor of Swansea), etc.; on the left, by Sir Charles Hastings, M.D., the Rev. E. B. Squire (Vicar of Swansea), Admiral Warde, etc. The vice-chair was filled by W. H. Michael, Esq., supported by Dr. Tunstall, Dr. Cormack, James French, Esq. (Mayor of Neath), Dr. Williams, etc.

At intervals during dinner, the celebrated harper, Mr. Williams, of Aberdare, played on the triple-stringed Welsh harp. After dinner, speeches and glees enlightened and enlivened the party. The following is a list of the toasts:—

1. THE QUEEN.

The PRESIDENT, in proposing this toast, said that within the last few days the Queen had conferred honour on two of the oldest and best members of the Association: he alluded to Sir John Forbes and Sir James Bardsley. [Cheers.] Her Majesty had formerly given proof of her regard for the profession, by honouring one who was very dear to them: he referred to Sir Charles Hastings, a gentleman who was an ornament to the profession, and eminently deserving of every honour. [Cheers.] He (Dr. Bird) was sure he need not appeal to their loyalty to do justice to the toast, for British loyalty, like the British oak, was indigenous to the soil, and he hoped that it would be the characteristic of Englishmen as long as the world lasted. [Cheers.] The toast was drank with every demonstration of loyalty.

Tune, "God save the Queen".

2. PRINCE ALBERT AND THE ROYAL FAMILY, by the President.

3. THE BISHOP AND CLERGY, by the President. The Rev. S. Davies returned thanks.

4. THE ARMY AND NAVY, by the President. Admiral Warde and Mr. Soden returned thanks.

5. THE MEMBERS FOR THE COUNTY, by the President.

6. THE MEMBER FOR THE BOROUGH OF SWANSEA, by the President. J. H. Vivian, Esq., M.P., returned thanks. He congratulated the members of the Association on their visit to Swansea; and expressed the pleasure which it would afford him to be able to forward the parliamentary business of the Association.

7. THE PRESIDENT, by J. H. Vivian, Esq., M.P. Dr. Bird returned thanks.

8. THE PRESIDENT OF THE COUNCIL, in a feeling and eloquent speech by Dr. Conolly.

Sir CHARLES HASTINGS on rising was greeted with enthusiastic cheers. He said that he felt most grateful, deeply grateful, for the manner in which Dr. Conolly had thought fit to introduce him to the company, and for the kind heartfelt manner in which they had responded to the toast. He did feel that upon this occasion he had received a greater degree of approbation from his brethren, than in his conscience he thought he had deserved

* The instrument is made by Mr. Becker, 9, Little Tichfield Street.

[Cries of "No, no."] But whether he was mistaken or not in the estimation of his labours, he did not hesitate to say that it was one of the proudest distinction to which a member of his profession could aspire, to live in the minds and enjoy the good will and the approbation of nearly 2000 members of his brethren. [Cheers.] Whatever had been the labours, the anxieties, and the cares which had been brought on him by the position to which he had been called, as one of the founders of this Association, they had been more than repaid by the manner in which his humble services had been approved. Indeed, he could not but feel that, whatever distinction had been conferred on him, he owed it mainly to the estimation in which his services had been held by the profession. [Cheers.] It was now full twenty-one years since he became the servant of this Association. His hairs had grown grey, and his locks had been thinned in that period; but he trusted that his heart was still warm in the cause, and whatever energies he may still possess, they would be devoted to its promotion. And although he might say, "*Non sum qualis eram*," still, as long as he had life, his energies should be devoted to the service of the Association. [Cheers.] The period of twenty-one years which had passed must remind them that if much had been done, much more was required of them. The Association had gone through the trying period of infancy, and of adolescence; it had now arrived at the age of manhood. They were, therefore, called upon now more than ever, one and all, to push forward the noble cause in which they were engaged. He was happy to see the zeal which animated especially the younger members of the Association, and if he sometimes proved a "drag" on them, he was bound to admit that the go-a-head system within certain limits was the best to be adopted by the Association. [Applause.] And although they would always find him ready to stand out against unnecessary innovations, still he would be ever ready to go with them when their object was to render more perfect the organisation of the Association. The future destiny of the Association now depended mainly on the younger members. If they were imbued with the noble objects which it was calculated to effect, no power could prevent progress, or retard a destiny which was as high as it was great. [Applause.] If the Association fell, it must fall by intestine disunion. Peace and harmony were the objects they had in view, and he trusted that the medical profession would always have such an inscription as that placed on their banners. The state of the medical polity was now such as to be unworthy of the civilisation of the age. The cooperation of laymen of local influence was therefore an important means of securing success. At the meeting of the Branch at Swansea last year, he well remembered the promises of the son of the hon. Member for Swansea to render them his assistance. Such aid from various localities was most acceptable, and its effect was exemplified in the recent interview they had had with Lord Palmerston. The first gentleman that he saw at his post on that occasion was the son of the hon. Member for Swansea. [Cheers.] The public were now sympathising with them, and it was that which had at length prevailed on the Government to acknowledge that the state of the medical polity was not worthy of its civilization, and both Lord Aberdeen and Lord Palmerston had at last promised to take up the question with the view of bringing about a better state of things. [Hear.] He was now convinced, therefore, that the long-agitated question of medical reform was at last about to be taken up in earnest, and when disposed of, the exertions made by this Association would not only shed a lustre on it, but add, to use a figure of speech, another wreath to deck its brow. [Cheers.] Sir Charles then referred in eloquent terms to the claims of the Medical Benevolent Fund and the Medical College, and concluded by making a powerful appeal to the members to unite and conquer, and not leave the business of the Association to be performed by a few. If they co-operated heartily, they would conquer all difficulties, ennoble their own names, and render important services not only to the profession, but to suffering humanity. [Loud cheers.]

9. The PRESIDENT-ELECT, Mr. WILSON, by Dr. Howell.

10. The MAYOR OF SWANSEA, by Sir C. Hastings. J. J. Strick, Esq. returned thanks.

11. The MEDICAL BENEVOLENT FUND and Mr. NEWNHAM, by the Rev. E. B. Squire. Dr. Tuke, in the absence of Mr. Newnham, returned thanks.

12. The MEDICAL BENEVOLENT COLLEGE, and Mr. PROPERT, by P. Grenfell, Esq. Mr. Propert returned thanks.

13. The EX-PRESIDENT, Dr. OGLE, by Dr. Morris.

14. The MONMOUTHSHIRE AND SOUTH WALES BRANCH, and Dr. MORRIS ITS PRESIDENT, by Dr. Tunstall. Dr. Morris returned thanks.

15. SUCCESS TO THE JOURNAL, AND THE HEALTH OF Dr. COR-

MACK, by J. French, Esq., Mayor of Neath. Dr. Cormack returned thanks.

16. Dr. HALL and Mr. PRICHARD, the gentlemen who had delivered the addresses in Medicine and Surgery, by Dr. Thomas Williams. Mr. Prichard, in the absence of Dr. Hall, returned thanks.

17. Mr. MICHAEL, the LOCAL SECRETARY, by Sir Charles Hastings, who thanked and complimented Mr. Michael and the profession in South Wales for their kind hospitality and successful arrangements for the meeting. Mr. Michael returned thanks.

18. Dr. EVANSON, AND THE MEDICAL PROFESSION IN IRELAND.

19. Dr. CONOLLY. Dr. Conolly returned thanks.

After a few appropriate words of parting, the company separated at midnight: and thus terminated the delightful and successful Swansea Meeting.

LIST OF MEMBERS PRESENT.

The following is a list of those members who entered their names in the book kept for the purpose.

ABERGAVENNY. F. C. Batt, Esq.; E. Y. Steele, Esq.
 AMMAN IRON WORKS, CARMARTHENSHIRE. John Jones, Esq.
 BATH. George Norman, Esq.; John Smith Soden, Esq.; James Tunstall, M.D.
 BAYSWATER. Thomas Workman, Esq.
 BIRMINGHAM. T. W. Williams, Esq.
 BLAINA IRON WORKS, MONMOUTHSHIRE. Joseph Hinton, Esq.
 BODMIN. Theodore Boisragon, M.D.
 BOLTON. J. Black, M.D.
 BRISTOL. J. G. Davey, M.D. (Northwoods); Augustin Prichard, Esq.; S. H. Swayne, Esq.
 CARDIFF. W. T. Edwards, M.D.; Edward Evans, Esq.
 CARMARTHEN. Henry Lawrence, M.D.
 CHELTENHAM. A. W. Gabb, Esq.
 CHEPSTOW. Thomas King, Esq.; Trevor Morris, M.D.
 CHIPPENHAM. Charles Bailey, Esq.; William Colborne, Esq.
 CHISWICK. Harrington Tuke, M.D.
 CLIFTON. George Rogers, M.D.; T. L. Surrage, Esq.; W. C. Trotman, M.D.
 CLYDACH, BRECON. R. Jenkins, Esq.
 COWBRIDGE, GLAMORGANSHIRE. Charles Sylvester, M.D.
 CWMAVON, GLAMORGANSHIRE. F. M. Russell, Esq.
 DARTMOUTH. R. F. Burroughs, Esq.
 FARNHAM. William Newnham, Esq.
 FERRYHILL, DURHAM. Hugh Clark, M.D.
 GLAN-TWRCH, GLAMORGANSHIRE. W. Price, Esq.
 GLYN-NEATH, GLAMORGANSHIRE. F. G. Evans, Esq.
 GREENHITHE. J. S. Seccombe, Esq.
 HANWELL. John Conolly, M.D., D.C.L.
 HEREFORD. Charles Lingen, M.D.
 KIBWORTH, LEICESTERSHIRE. John Marriott, Esq.
 LEICESTER. Thomas Paget, Esq.
 LLANDILO. John Jones, Esq.; David Prothero, M.D.
 LLANELLY, CARMARTHENSHIRE. B. Thomas Esq.
 LONDON. John Bowling, Esq. (Hammersmith); John Rose Cormack, M.D. (Putney); Samuel Hare, Esq.; Alexander Henry, M.D.; John Probert, Esq.; Francis Sibson, M.D.
 LOUGHOR, CARMARTHENSHIRE. T. W. Jones, Esq.
 MAESTEG, CARMARTHENSHIRE. James Lewis, M.D.
 MANCHESTER. Thomas Radford, M.D.; George Southam, Esq.
 MERTHYR TYDVIL. G. Davies, Esq.; T. J. Dyke, Esq.; John Russell, Esq.; H. S. Wharton, Esq.
 MORRISTON, SWANSEA. J. Cook, Esq.
 NEATH, GLAMORGANSHIRE. James French, Esq.
 NEWPORT, MONMOUTHSHIRE. W. James, Esq.; W. W. Morgan, Esq.
 ODIHAM, HANTS. John McIntyre, M.D.
 OSWESTRY, SALOP. Peploe Cartwright, Esq.
 OXFORD. R. J. Hansard, Esq.; James Adey Ogle, M.D. (Retiring President).
 PONTYPOOL, MONMOUTHSHIRE. John Williams, Esq.
 READING. Charles Cowan, M.D.
 RISCA, MONMOUTHSHIRE. E. Robotham, Esq.
 RUGBY. Abraham Duke, M.D.
 ST. ANDREWS. George E. Day, M.D.
 SIRHOWY, MONMOUTHSHIRE. N. Coats, Esq.
 STOCKPORT, CHESHIRE. George Turner, M.D.
 SWANSEA. George Gwynne Bird, M.D. (President); T. A. Essery, Esq.; W. P. Evans, Esq.; J. G. Hall, Esq.; Edward Howell, M.D.; W. H. Long, Esq.; W. H. Michael, Esq.; D. Nicol, M.D.; Thomas Williams, M.D.

STRATFORD-ON-AVON. David Rice, Esq.
 TAUNTON. Henry Alford, Esq.
 TIMBURY, SOMERSET. James Crang, Esq.
 TORQUAY. C. Radclyffe Hall, M.D.; C. B. Nankivell, M.D.
 WORCESTER. Sir Charles Hastings, M.D., D.C.L.; J. P. Sheppard, Esq.
 YSTALFYFER, NEAR SWANSEA. James Rogers, Esq.

NEWS AND TOPICS OF THE DAY.

MEETING OF PROVINCIAL PHYSICIANS.

A meeting of the provincial physicians attending the Association at Swansea, was held at the Guildhall, on Thursday morning, August 11, Sir Chas. Hastings in the Chair. Among the gentlemen present, we noticed Dr. Day, of St. Andrews, Dr. Howell and Dr. T. Williams, of Swansea, Dr. Morris, of Chepstow, President of the South Wales Branch of the Association, Dr. Duke, of Rugby, Dr. Lawrence, of Carmarthen, Dr. Sylvester, of Cowbridge, and Dr. Tunstall, of Bath.

The following report was then read.

REPORT.

The Committee of British Graduates practising as provincial physicians, appointed at Oxford "to confer with the Royal College of Physicians in relation to the proposed new charter", in presenting their report, beg to congratulate you on the prospect now held out by the Government of a speedy settlement of the question of Medical Reform.

Your Committee report that immediately after the general meeting of provincial physicians at Oxford, your Honorary Secretary, Dr. Tunstall, transmitted the resolutions, then unanimously adopted, to the Royal College.

In November 1852, Dr. Hawkins, the Registrar of the College, communicated with your Secretary, and in a letter which your Committee considered highly satisfactory, as showing that the College were most anxious to do justice to the provincial physicians *de facto* in practice (both in reference to the fees, and the exorbitant stamp duties on their diplomas), trusted that the College would meet with the cordial cooperation of the British Graduates in the attempt to obtain the proposed new charter. Your Committee resolved, with the concurrence of Dr. Hawkins, to give publicity to this important document, they accordingly caused it to be printed, with an address from themselves, in order that it might be freely circulated among the parties interested; copies were sent to the medical periodicals, and to the Universities of Great Britain and Ireland.

Shortly after the publication of these letters, the physicians of Sheffield addressed the following letter to the Charter Committee of the College.

"We, the undersigned, at present engaged in Sheffield, in the practice of our profession as physicians only, beg to draw the attention of the Charter Committee to the fact that we have paid already to the Government of this country, a very large sum for stamp duty on our diplomas. We therefore request the College seriously to urge on the Secretary of State for the Home Department the justice of remitting the stamp duty to all those at present engaged in the practice of their profession as physicians only, who may be admitted into the Royal College of Physicians of England, within one year after the granting of the proposed new charter."

A correspondence took place between Dr. Tunstall, on the part of your Committee, and Dr. Wood, the secretary to the Royal College of Physicians of Edinburgh, which led to the presentation of a petition from that learned body to the House of Commons in February 1853; a copy of this petition appeared in the ASSOCIATION JOURNAL, No. 7, p. 141, and urges the following considerations on the legislature.

"That it appears unfair and injurious that the graduates of Scotch Universities should pay three taxes: *first*, on graduation; *secondly*, on admission to the Royal College of Physicians of Edinburgh; and *thirdly*, on admission to the Royal College of Physicians of England. That it also appears that the exemption of the London University, and the Queen's University of Ireland, which are new institutions, entirely supported at the public expense, is calculated to injure the schools of medicine in Scotland by creating an invidious distinction which ought not to exist."

A copy of the abovenamed petition, with the address issued by your Committee, was transmitted to the Secretary of State for

the Home Department, and by him was courteously acknowledged.

Your Committee having learned from authentic sources that the government were not prepared to deal with the question of a remission of the stamp duties during the present session of Parliament, and that the charter to the College was likely still further to be delayed, resolved to address Lord Aberdeen on the subject, and in July last transmitted the following memorial to that nobleman:—

"To the Rt. Hon. Lord Aberdeen, First Lord of Her Majesty's Treasury.

"The humble memorial of the undersigned graduates in medicine of British universities, appointed at a meeting of provincial physicians held at Oxford on July 22nd, 1852, to confer with the Royal College of Physicians in relation to the proposed new charter, humbly sheweth,—

"That your memorialists have heard with extreme satisfaction that it is the intention of Her Majesty's Government to advise Her Most Gracious Majesty to grant a new charter to the Royal College of Physicians, whereby the provincial physicians now practising in England and Wales, without the diploma of the College, may be incorporated as members of that body on payment of certain fees and stamp duties. Your memorialists therefore humbly pray,—

"First. That the said charter may be granted to the said Royal College.

"Secondly. With a view to induce all provincial physicians in practice as aforesaid to avail themselves of the privilege of incorporation proposed by the said charter during the first year after Her Majesty shall be graciously pleased to grant the same—an event your memorialists earnestly desire,—your memorialists humbly pray that the stamp duties payable on diplomas issued to provincial physicians already in practice may be reduced; your memorialists being decidedly of opinion that, however desirable the new charter may be to those who may hereafter practise as provincial physicians, those already in practice will not be bound by its provisions; in other words, that the taking of the new diploma will be a purely voluntary act on the part of those already in practice as physicians in the provinces. Having already paid a large stamp duty on their diplomas as doctors of medicine, your memorialists humbly pray that the case of the provincial physicians, graduates of recognised British universities, may be taken into the consideration of Her Majesty's Government.

"And your memorialists will ever pray", etc.

This memorial was signed by every member of your Committee, and transmitted to his Lordship, who courteously acknowledged its receipt.

With reference to the stamp duties, your Committee would urge this consideration, that, in all other professions and trades in which stamp duties are required to be paid, the imperial government affords its protection to the legitimate pursuer by restricting the exercise of these callings to those only who are licensed by the payment of such duties. In the profession of physic, however, no such protection is afforded; the ignorant and unblushing pretender can with impunity usurp the titles which belong only to the profession, the better to cloak his villainies and conceal his crimes; and the government derives a large revenue from the sale of quack medicines, and lends its aid to the most detestable robbery of the public induced by their sale, whereby the most obscene and indecent advertisements, destructive alike to modesty and virtue, are daily obtruded in the public prints. Your Committee, therefore, is strongly of opinion that the legislature has no right to impose stamp duties on the license or diplomas of medical men, until it is prepared to protect the profession against unlicensed pretenders, and the public against the evils of empiricism; and your Committee earnestly hope that not only the provincial physicians, but the profession generally, will earnestly contend for an exemption from stamp duties, or for that protection from unlicensed competition which the payment of such duties entitles them to expect.

It was moved by Dr. WILLIAMS, seconded by Dr. SYLVESTER, and resolved,—

"That the report now read be received and adopted."

Dr. LAWRENCE moved, and Dr. DUKE seconded,—

"That the Committee be reappointed, with the addition of Dr. THOS. WILLIAMS, and that they have power to add to their numbers; that the best thanks of the meeting be given to Sir Charles Hastings and the members of the Committee for their services; and that they present a report at the next meeting at Manchester."

It was proposed by Dr. TUNSTALL, seconded by Dr. HOWELL, and carried,—

"That the best thanks of the provincial physicians are due, and hereby given, to Lord Dudley C. Stuart, M.P., for his kind attention to their interests."

ROYAL COLLEGE OF SURGEONS.

(House of Commons, Tuesday, August 16.)

The following Returns were applied for by Mr. EWART.

Returns of the number of persons who presented themselves for examination to be admitted Members of the Royal College of Surgeons of England, in each year, from the 11th day of July 1834, to the 18th day of August 1853, stating the number of rejections in each year, the average duration of each examination, the subjects examined on, the average age of candidates, the number educated at each medical school in Great Britain and Ireland, or foreign schools, and the number rejected belonging to each school. Of the number of persons admitted to the Fellowship of the Royal College of Surgeons of England, in the years 1843-44, and the rules observed by the Council in regulating their admission. Of the number of persons who presented themselves for the examination of Fellowship in each year, since the 1st day of January 1845, to the 6th day of July 1852, stating the number who were Members of the College, the number of rejections in each year, together with the number refused examination. Of the number of candidates for the classical examination required for the Fellowship, since the 1st day of January 1850, to the 18th day of August 1853, stating the number who were already Members of the College, the number of Members rejected for this examination, together with the gross amount of rejections and the subjects examined on. Of the number of candidates for examination for the Fellowship, from the 6th day of July 1852, to the 18th day of August 1853, stating average age, and number rejected. Of the number of members of the College of Surgeons of England admitted for the fellowship by seniority on payment of ten guineas, since the 6th day of July 1852, to the 18th day of August 1853, stating the number refused admission and the number on whose admission divisions of the council took place. Of the various fees received by the Council and Court of Examiners. Of a detailed statement of the annual income and charges, and of the actual receipts and payments of the College, during the last three years, ending the 18th day of August 1853. Of the different professors, office bearers, and servants of the College of Surgeons of England, from the 1st day of January 1834 to the 10th day of August 1853, the names of the different officers, together with the amount of salary or gratuity paid or voted to each and every such professor, officer, or servant, with the dates of appointment, dismissal, or resignation. Of the different editions of the bye-laws of the College of Surgeons of England, regulating the education and examination of candidates for the fellowship and membership, from the 1st day of January 1834 to the 18th day of August 1853. Of the number of medical schools and hospitals from which the recognition of the College of Surgeons has been withdrawn within the three last years, ending the 18th day of August 1853, together with a list of schools and hospitals that have applied to be recognised as schools of instruction for medical students in the same years, and the causes which led to the withdrawal of any schools or hospitals. Of the number of volumes purchased for the Library of the College of Surgeons from the 1st of January 1834 to the 10th of August 1853, together with a list of the number presented. Detailed accounts of expense of the Library of the College of Surgeons of England for the last three years, ending the 18th day of August 1853. Of the expense of Museum of the College of Surgeons of England for three years, ending the 10th day of August 1853. Of the expense of entertainments to the Council and Court of Examiners of the College of Surgeons of England in each year for the three last years, ending on the 18th day of August 1853. And, of all monies paid to each Member of the Council and Court of Examiners within the last three years, ending the 10th day of August 1853, stating the amount paid in each year.

VACCINATION EXTENSION BILL.

The Vaccination Extension Bill was read a third time, and passed in the House of Commons, on Monday last. On Tuesday the House of Lords, on the motion of Lord Lyttelton, approved the amendments and alterations which had been introduced into the Bill during its progress through the lower House.

COMPLIMENT TO THE MEDICAL PROFESSION. The Lord Chancellor, on the recommendation of the Lord Lieutenant, the Earl of Warwick, has nominated William Sands Cox, Esq., a deputy Lieutenant, to the commission of the peace for the county of Warwick.

ROYAL COLLEGE OF SURGEONS:—LIBRARY. According to annual custom, the Library of the Royal College of Surgeons will be closed during the ensuing month of September, for the purpose of cleaning and arranging the books.

UNIVERSITY OF LONDON. PASS LIST. M.B.: FIRST EXAMINATION, 1853. *First Division:* Robert Henry Bartrum, Thomas Edwin Burton Brown, Guy's Hospital; St. John Edwards, University College; Joseph Ravenscroft Elsey, Guy's Hospital; David Conway Evans, King's College; James Fawcus, Wm. Price Jones, and Henry Walter Kiallmark, University College; Wm. Whytehead Morris, Leeds School of Medicine; George Mayris Pittcock, Guy's Hospital; Augustus Pout, King's College; Frank Powell, St. Bartholomew's Hospital; John Dewherst Scurrah, University College; Fred. Porter Smith, King's College; Clement Williams, Guy's Hospital. *Second Division:* George Aug. Fulcher, St. Bartholomew's Hospital; Edward Ash Hadow, Bristol Medical School; Robert George Hardwick, Leeds School of Medicine; Vaughan Henry Alex. Holberton, King's College; Riners Mantell, London Hospital; James Lewis Sjordet, Wm. Isaac Spencer, University College; James Howard Thornton, King's College.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. MEMBERS admitted at the meeting of the Court of Examiners on July 18th:—Frederick Tydd Abbott, Nenagh, co. Tipperary; Edward Jacomb Asbury, Enfield, Middlesex; Thomas Bramah Diplock, Chelsea; Decimus Filius De Hodgson, Carlisle; Chas. Julian Jackson, Macclesfield, Cheshire; James Scarborough Loe, Leeds, Yorkshire; Robert Modlin, Castleside, Durham; Frederick William Moore, Charlmount Terrace, Dublin; Charles James Roe, Greenock, Scotland; John Smith, Caseley, Staffordshire.

July 22nd:—Robert Brown, Wintershields, Cumberland; William Lee Dawson, Cloughran, co. Dublin; William Henry Jones, London; John Macloghlin, Liverpool; Edward O'Neill, Michellstown, co. Cork; John Segar, Ainsdale, near Southport, Lancashire; George Moulas Slaughter, Farningham, Kent; Evan Pierce Williams, Denbigh, North Wales; Isaac Mennell Williams, York; Thomas Windsor, Piccadilly, Manchester; Christopher Young, Yarm, Yorkshire.

July 25th:—John Barnett, Moneymore, co. Derry; William Collins, Kingston, co. Dublin; George Craven, New Worthy, Yorkshire; Chamney Graves Irwin, Raphoe, co. Donegal; Robert McKibbin, Ballymacarrett, near Belfast; Archibald Nicolls, Kilmakenny, co. Leitrim; William Brown Pepler, Tinhead, Devozes; Henry Tyrwhit Smith, Melton Mowbray.

July 20th:—John Carey, Shacklewell; Henry East, Sydney, South Australia; William Noble, Linton, Herefordshire; Edward Prentice, North Walsham.

LICENTIATES IN MIDWIFERY admitted at the meeting of the Board of Examiners on July 6th:—John Jones, Swansea; John William Howard, Fenchurch Street; Cecil Calvert Cogan, Winsley, Wilts; Henry Joseph Hurschell Griesbach, Pocklington; William Bass Smith, Louth, Lincolnshire; Peter William Rolston, Devonport; George Elin, Kent Terrace, Regent's Park; Joseph Ewart, Holmhead, Cumberland; Daniel Gwynne, Halsey Terrace, Sloane Street; William Hall, Ryath Thirsk, Yorkshire; Henry Stiles, Spalding, Lincolnshire; Clarence Cooper, Brentford.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

HESLOP, Dr., Physician to the Queen's Hospital, Birmingham, appointed Joint Professor of Materia Medica in Queen's College.

*PEMBERTON, Oliver, Esq., Surgeon to the General Hospital, Birmingham, appointed a Demonstrator of Anatomy in Queen's College.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXXIV.

LONDON: FRIDAY EVENING, AUGUST 26, 1853.

New Series.

ADVERTISEMENTS.

Three lines and under	-	-	-	20	2	6
Every additional line	-	-	-	0	0	6
Half-column	-	-	-	1	10	0
A whole column	-	-	-	2	15	0

A line contains ten words, so that any one can calculate the cost of an Advertisement.

Advertisements ought to be delivered at the office on the Wednesday preceding publication, and paid for at the same time.

Post-Office orders are to be made payable to THOMAS JOHN HONEYMAN, 37, Great Queen Street, Lincoln's Inn Fields, London.

TO CONTRIBUTORS. We have received within the last week several MSS. accompanied by a request for payment if they were inserted. We therefore take this opportunity of stating that no literary work is paid for unless executed in accordance with a previous agreement. To secure unity of plan and harmony of sentiment, it is essential that the editor communicate directly and frequently with those who assist him.

Letters referring to the commercial department ought to be addressed to MR. HONEYMAN, 37, Great Queen Street, Lincoln's Inn Fields; and communications for the Editor to Essex House, Putney, London, or to the Office. The Editor is generally at the Office on Wednesdays, from four to five P.M.

MEDICAL METEOROLOGY.

At the present time, when Physiology, Chemistry, and the Revelations of the Microscope are so extensively pressed into the service of medical observers, and made to elucidate the origin and nature of various diseases, it would be strange if we remained contented with vague notions on the important subject of Meteorology in its relations to medicine. To dilate upon its great importance would be a mere waste of time; for the fact that, in all times and places, the common sense of mankind has ascribed to atmospheric changes a serious effect upon the health of human beings, is just as clear and unquestionable as another fact—that, of the nature and operation of atmospheric changes upon the human body in health and disease, we have many guesses, some vague notions, but *no strict sciences*. In this interesting region of inquiry, that inductive science which has explored the bowels of the earth, and has classified the productions of its surface, has hitherto done little. The atmosphere and its changes, though immediately surrounding us, and constantly affecting our daily experience, are less understood than the movements of distant stars and planets!

Our present object is, I. To notice the present vague condition and defective study of Meteorology in its medical aspect; and II. To suggest the modes in which this interesting branch of study may be more scientifically and advantageously cultivated. Great are the difficulties—as in all beginnings; but we believe that, by a judicious division of labour, earnest cooperation, and a strict adherence to the inductive method of research, victories may be achieved here, as in other departments of science.

I. We already have observations on Meteorology in some sort of connexion with disease and death; but they are not definite enough for our purpose. This is the first point on which we must insist. Let us first notice the Registrar-General's weekly tables of mortality in London. These give

the week in which the deaths were registered; not the times when the deaths occurred. What can be induced, in a medico-meteorological point of view, from such facts?—Nothing. Let us suppose a case:—that a patient was seized by an attack of *bronchitis* on the seventh of April in any year, and during the prevalence of a cold north-easterly wind; that the patient died on the fourteenth; and that on the seventeenth the death was registered; but meanwhile, that, on the thirteenth, the wind had changed to a mild south-westerly breeze: it is obvious that the registration of the death on the seventeenth could have no value as a medico-meteorological fact. The dates especially wanted are those of the first seizure, and also of the changes of weather, and the symptoms during the progress of the disease.

The Registrar-General, in his returns for the week ending March 19th, 1853, remarks that—"The effect of sudden changes of temperature does not immediately become perceptible to its full extent in the register of deaths." The fact is, we want, for medical purposes, a correct registration of the very day on which the attack of disease commenced, and of the meteorological observations of *that day*, side by side; and this will be the new and important feature of the tables to be inserted in this Journal. Obviously, medical men are the only persons who can be competent to make the two-fold observations on meteorology and pathology which we require. It must always be kept in mind that our observations have not a *general* scientific purpose; but a *specific* aim—the advancement of medical science.

Dissatisfaction with *vague observations* is common to all who have thought on the relations of Meteorology with Pathology. Dr. Addison of Maidstone, and Dr. Moffat of Hawarden, in their excellent letters inserted in this Journal (pp. 80, 139), have already insisted on the necessity of *daily* observations. As examples which may serve to indicate the course to be pursued, we may briefly allude to the valuable papers by Dr. Tripe, in the *Medical Times* (1848-49). During a long and extensive experience of scarlet fever, Dr. Tripe has observed that, in London, a high barometrical pressure is frequently coincident with a low rate of mortality from scarlatina; that extreme and long-continued variations of the barometer indicate a condition of the atmosphere adverse to the progress of the disease; that the mortality from scarlatina is low in a cold January, and *vice versa*; but that, in the summer quarter, a temperature lower than the average is somewhat favourable to increased mortality from scarlatina. This is not the place to inquire into the certainty of these results of Dr. Tripe's researches; but we refer to them as good specimens of that kind of investigation which is required with regard to the connexion existing between meteorological changes and several diseases. For another example, we may refer to the valuable paper of Mr. R. D. Grainger, "On the Influence of Noxious Effluvia on the Origin and Propagation of Epidemic Diseases"—at pp. 164, 184 of the ASSOCIATION JOURNAL. We would suggest that, in addition to the *local* causes, so well described by

Mr. Grainger, it will be interesting, in future, to investigate the simultaneous influence of *meteorological* causes; to ascertain the atmospheric conditions by which a general tendency to certain diseases is induced, becoming most fully developed wherever it is favoured by local circumstances. That local and atmospheric conditions often concur to produce disease, is already clearly manifest. The local nuisances which would be harmless during a hard frost, may spread disease and death over a neighbourhood during the dog-days. Mr. Grainger and other sanitary inquirers have made out the strongest possible case to prove the influence of *local* causes on the zymotic class of diseases: further inquiries into the *concurring meteorological causes* are now required. It has been frequently observed that, while local circumstances have remained unchanged, the propagation and progress of epidemic diseases have varied considerably. A disease of this class has appeared in a certain locality, has raged with greater or less violence for a certain time, then has disappeared, again to be developed under certain conditions. What are these conditions? Can they be clearly

explained by meteorological observations? These are instances of the numerous interesting queries to be answered by the medical meteorologist; but in order to give a character of certainty to his answers, he must make his observations in a strict and definite method, which we have now to explain.

II. We cannot open our suggestions on improved medico-meteorological observations better than by a quotation from the *British and Foreign Medico-Chirurgical Review* (No. xv)—“The subject is beset with difficulties; and, in order that *correct results* may be obtained, the investigation must be conducted with logical precision.” Before entering into details, we may give, as an example of the method of observation required, the table constructed by Dr. Moffat, based upon his practice in 1851-52, and read at one of the meetings of the British Meteorological Society. It gives observations of a few diseases, with their percentage of prevalence, during the increase and decrease of readings of the barometer; with observations on the winds, and on the presence of ozone in the air:—

Name of Disease.	Increase of barometer readings.	Decrease of barometer readings.	Increase of tem- perature.	Decrease of tem- perature.	Ozone.	No Ozone.	N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.
	per cent.	per cent. 80.0 & 10.0 day after.	per cent.	per cent.	percent.	percent.	p. c.	p. c.	p. c.	p. c.	p. c.	p. c.	p. c.	p. c.
Paralysis	20.0		40.0	60.0	90.0	10.0	0.0	0.0	0.0	1.7	0.7	3.9	0.0	0.9
Epistaxis	37.0	74.0	12.0	75.0	50.0	25.0	2.7	7.6	0.0	3.4	0.0	0.6	0.0	1.4
Toothache.....	19.0	90.0	29.0	65.0	77.6	22.3	5.4	11.5	4.7	22.0	11.0	9.1	5.0	13.0
Rheumatism	28.5	71.4	28.5	71.4	85.7	14.2	0.0	0.0	0.0	0.0	0.7	1.9	0.5	0.9
Pleurisy	50.0	50.0	50.0	50.0	100.0	0.00	0.0	0.0	0.0	0.0	0.0	0.0	0.5	1.4
Per-centage of deaths from all causes	40.4	50.6	48.4	57.6	68.7	31.2	35.1	42.3	52.3	25.5	25.1	24.1	36.0	76.2

Among the interesting points for consideration presented by the above table, we can notice only one—the increase of deaths from the southern or warm towards the northern or cold points of the compass. It appears that the greater number of diseases occur in the equatorial, and the greater number of deaths in the northern or polar points. The probable connexion between this indication and the presence or absence of ozone, forms one of the important points left for future researches. The rotation theory of the winds, as developed by Professor Dove of Berlin, has been adopted as the basis of the observations made by Dr. Moffat. Of this theory, especially in its medical aspects, some account will be given in another paper, as it would occupy too much space in these introductory observations.

Dr. Moffat, in his papers on Medical and Agricultural Meteorology and Atmospheric Ozone, read at meetings of the British Meteorological Society, has arrived at very interesting conclusions. Our readers are no doubt aware that, according to the rotation theory, it is believed that there are two currents of air in each hemisphere of the globe, viz. the polar, which blows from the poles to the equator, and the equatorial, which returns from the equator to the poles. It is supposed that, were the earth at rest, these currents would have a course direct from north and south to the equator; but as the earth turns upon its axis, they are influenced by its motion, and veer; the polar in the northern hemisphere from a north to north-east and east, and in the southern hemisphere from a south to a south-east and east

wind. Within the tropics, these currents form the lower and upper trade winds; the former, the polar, blowing (in the northern hemisphere) from north-east to south-west, and the upper, the equatorial, from south-west to north-east. As the upper current approaches the polar latitudes, by being cooled, it gradually descends to the surface of the earth; and in latitudes north and south of 28 degrees, or thereabouts, the two currents blow side by side, and constantly endeavour to displace each other. In the northern hemisphere, the polar occupies the north of Asia, and north-east of Europe; while the equatorial is more commonly prevalent on the western coast of the latter continent. Dr. Moffat (as stated in his papers) has observed that ozone is peculiar to the equatorial points of the compass—that is, in points between south-east and north-west by way of south and west; and that it is not detected in the polar current, viz. in points between north-west and east by way of north and north-east. He has also observed that the greater number of diseases occurs when the wind is in equatorial or ozone points; and that the greater number of deaths take place when the wind is in polar or no ozone points. He attributes the more frequent occurrence of diseases to the frequent atmospheric changes that take place while the wind is in southern points, as indicated by the more extensive and more frequent oscillations of the barometer. And the greater number of deaths in the polar points, he concludes to be the result of reduction of temperature, and gives the following as a type of general statement:—

cesses, and states that he believes that it forms the basis of all processes in these latitudes. At the termination of an ozone period, the wind veers through north-west to north, north-east, and east points of the compass. The sky becomes cleared of clouds, and the barometer attains its maximum readings. If when the wind is east the barometer remains stationary, or increases in its readings, the wind is again perceived to set in from the north, the same process is repeated, and there are no new cases of disease, and there is no ozone. If, however, when the wind is east, a case of toothache, neuralgia, diarrhoea (with or without cramps and vomiting), convulsions, epilepsy, apoplexy, hæmorrhage, epistaxis, hæmoptysis, or premature uterine action, should occur, the barometer readings decrease, either immediately or in a few hours afterwards. The equatorial current sets in as a north-west wind, or a current from more southern points, and ozone is detected. When the barometer readings begin to decrease with the occurrence of the diseases, cirri are observed to advance from points of the horizon between north-west and south-east, the sky becomes overcast, and there may be rain. Should the barometer read-

ings begin to increase, while the wind is in the south points, the current will gradually veer to west and north-west points, and ozone will again disappear; but should any one of the above diseases take place while the wind is in north-west points, the barometer readings will again decrease, the wind will increase and fall back upon southern points, ozone will increase in quantity in proportion to the force of the current, and the number of diseases will be greater or less, just as the equatorial has the ascendancy for a longer or shorter period. Dr. Moffat also observes that clouds of the cumulo-stratus, and cumulo-cirro-stratus class, are more common when the wind is in south-west and north-west, than when it is in other points of the compass; and that hail and snow showers seldom occur with any other direction of the wind. He also observes that apoplexy, epilepsy, and sudden deaths, invariably occur with a prevalence of hail and snow showers.

We may now briefly explain the use of the several columns of the Meteorological Tables, henceforward to be inserted in this Journal. We insert an outline, in order that our description may be better understood:

Place, lat. long. height.	Month and Day.	Barometer		Thermometers.				Wind.	Amount of Ozone.	Amount and class of cloud for day.	Hall, snow, sleet, fog, frost.	Thunder, lightning, thunder and lightning, aurora, haloes, etc.	Rain.		Diseases.		Deaths.		Name of Observer.					
		9 A.M.	3 P.M.	Maximum.	Minimum.	Maximum in Sun.	Minimum on Grass.						Mean daily temperature.	Range of temperature.	Temp. of dew-point.	Degree of humidity.	Mean direction for day.	Mean force.		No. of	Name and time of commencement.	No. of	Cause and time of death.	
	14 Aug. S.																							
	15 M.																							
	16 T.																							
	17 W.																							
	18 Th.																							
	19 F.																							
	20 S.																							
No. of column		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	

N.B. The readings of the Barometer have been corrected for index-error and capillarity, and reduced to the constant temperature of 32 degrees Fahr. In column headed "rain fell on" the letter R denotes that rain fell on the day opposite to which the letter is placed. In column headed "amount and class of cloud" the contractions are the same as those used by the British Meteorological Society.

Columns 1 and 2 represent the pressure of the air by the barometric readings at 9 A.M. and 3 P.M. Liebig's researches on the evaporation of liquids through membranes, and his experiments on endosmosis and exosmosis, illustrate the effects of atmospheric pressure on the circulation of the blood, and the evaporation from the skin and pulmonary or bronchial membrane. The amount of evaporation from the skin and the lungs is modified by the temperature of the air and its hygrometrical condition, and, as the circulation of the blood and the absorption of the alimentary contents of the digestive canal are both accelerated by an increased amount of evaporation, we must admit the medical importance of the observations included in columns 3 to 10 inclusive. To give some instances:—it is owing to the dryness of the air at great elevations, that the evaporation from the skin and the consequently increased motion of the fluids within, produce oozing of blood from the gums, etc., during the ascent of high mountains.

It is a fact quoted from Edwards by Matteucci, that the quantity of cutaneous exhalation from the human body is, sometimes, ten times greater in dry than in moist air, and that it is doubled in passing from 32° F. to 64° F. It cannot be

doubted that such a transition as this must exert a very serious influence on health. During rapid falls of the barometer such as occur before thunder storms, effluvia arising from drains, cess-pools, privies, etc., are felt as more serious nuisances than at other times. This is owing to the rapid rarefaction of the air by diminished pressure. Such extreme and rapid falls of the barometer are frequently followed by hæmoptysis in some patients—the diminished pressure of the air giving rise to oozing of blood from the pulmonary membrane, and this is especially likely to occur, when a diminished temperature takes place to such a degree as to produce congestion of internal organs, by decreasing the determination of blood to the surface. The degree of humidity of the air has also a considerable influence on hæmorrhages from the mucous membranes.

As another example of the relation of atmospheric changes with human life, we may incidentally notice here, that rapid falls of the barometer should be observed with reference to precautionary measures in mines, where the diminished pressure of air allows fire-damp and other gases to escape more freely from crevices, etc., so as to endanger the lives of the miners.

Observations on ozone will be given in column 13, and must be regarded as very interesting and important. By careful observation and collection of a sufficient number of facts, we shall be able to determine the part which this substance plays in connexion with disease, and whether or not its presence in the air produces, as has been suspected, bronchitis, conjunctival ophthalmia, and other diseases. As the presence of ozone in the atmosphere is often coincident with a decrease of temperature, we cannot now say which of the two may be the real cause: and bronchitis is often known to occur when ozone is not detected in the air.* This is one of the problems to be solved by medico-meteorological observation.

The amount of cloud, in column 14, may be noticed as preventing the scorching effect of the sun's direct rays in the day-time and as modifying radiation during the night. It is also important to notice the prevailing class of cloud. For example, the appearance of *cirri* is generally indicative of a fall of the barometer; and this never takes place, as Dr. Moffat has observed, without sensible effects on patients labouring under certain diseases.

Storms of hail, snow, sleet, thunder and lightning, with the phenomena of frost, fog, aurora and zodiacal lights, will be noticed in columns 15 and 16. Columns 17 and 18 will be devoted to observations on the fall of rain.

It has been remarked that a great majority of cases of some diseases, are accompanied, or immediately preceded by a fall of the mercurial column; and this statement would suggest, that as *mean readings* of the barometer do not indicate the *sudden changes* which appear to be so productive of many diseases, they cannot suffice for *medical* meteorologists. The time of a *change* of weather, and the precise date of the commencement of disease, or of a change of symptoms, or of sudden death: these are the points on which we must especially fix our attention. With this object in view, the next four columns, 19, 20, 21, and 22, will be essentially important in a medico-meteorological aspect. They will record the number of deaths, causes of death, number of diseases and names of diseases, occurring under the notice, or in the district, of each observer. This will be the new and important feature of the observations inserted in our Journal, and these four columns, conjointly with the meteorological observations, must supply the data from which true conclusions may be deduced, respecting the connexion between atmospheric changes and the manifestation of diseases. Each observer is fully aware of the difficulty and importance of this department of his labours, and will, therefore, be doubly careful to render this part of the meteorological table correct and trustworthy. The Registrar-General has kindly allowed the Registrars of deaths in the respective districts, to furnish the observers with weekly information as to the number, dates, and causes of deaths; so that this information, together with the medical practice of the several observers, will afford ample facts with which to fill these columns.

Having thus explained the leading features of our scheme,

* Should any of our readers wish to make observations for themselves, carefully prepared ozone test paper, with full instructions, may be obtained, at moderate charge, of Mr. John Cox, 8, Rye Lane, Peckham, Surrey. The following is the mode of registering the quantity of ozone in the air, as followed by Dr. Moffat:—

If the test paper be not tinged brown in 24 hours 0.
If the test paper be perceptibly tinged brown in 24 hours 1.
If in 18 hours, 2; in 12, 3; in 10, 4; in 8, 5; in 6, 6; in 4, 7; in 2, 8; in 1, 9; and in $\frac{1}{2}$ hour to $\frac{1}{4}$ hour, 10.

we shall reserve some other considerations of practical details for future articles; but we may here express our hope, that a plan which promises to yield valuable data towards an extension of medical science, will be carried into operation with industry and perseverance. The zeal and hope of good and great results manifested by our coadjutors in the task, encourages us to believe that, in this humble beginning, we may lay the basis for an extended system of medico-meteorological observations, and that eventually by such a system, several truths now only dimly seen, lying among guesses and suppositions, may be established on sure scientific principles.

Some time before the appearance of the letters by Dr. Addison and Moffat (to which we have already referred), arrangements were made for the insertion of a medico-meteorological report in this Journal. For the plans, and for a large share of the practical measures necessary to carry them into operation, our readers are indebted to the Bedford observer. Assisted by those gentlemen who have kindly consented to contribute reports, especially by Dr. Moffat, of Hawarden, Dr. Barker has now brought all necessary arrangements near to completion, and it will be gratifying to our readers to know that our plans have been submitted to the notice of that eminent meteorologist, Mr. Glaisher, and have received his approbation.

It would be desirable to have reports from medical observers in each degree of latitude and longitude in England; but to accomplish this, twelve contributors would be necessary, a number too great for the space to which our tables must be restricted, and we are not aware that medico-meteorological observers could be found for every degree. As we have already said, we must employ the services of *medical* men exclusively, as observers; because our object in inserting meteorological tables in this Journal, is solely to render them conducive to the advancement of medical science, and improvement in practice—especially with regard to prophylactic measures against atmospheric changes.

Observations will be forwarded from the following places:

Place.	Latitude.	Longitude.	Height.	Observer.
Guernsey	49.33. 0 N	2.40. 0 W	123 ft.	Dr. Hoskins.
Ryde, I. of W...	50.45. 0	0. 4.46 W	110	B. Barrow, Esq.
Exeter	50.45. 0	3.41. 0 W	140	Dr. Shaper.
Uckfield	50.58.59	0. 5. 0 E	180	C.L. Prince, Esq.
Bedford	52. 8. 0	0. 1.51 W	100	Dr. Barker.
Grantham	52.54.52	0.36. 0 W	190	J.W. Jeans, Esq.
Hawarden	53.11. 0	3. 2. 0 W	260	Dr. Moffat.
Wakefield	53.40.50	1.30.26 W	115	W. Milner, Esq.

We would solicit the aid of other medical men who do not make regular meteorological observations: they may at least note from day to day the most striking barometric changes, and the dates of commencement of diseases, especially those which assume an epidemic character. This will require some care. Only clear cases of coincidence should be noticed. When possible—and it often will be—the precise *hour* of the seizure should be given; but when a true date for the commencement of a disease is not satisfactorily known, the case should be rejected on account of its uncertainty.

Every medical man may contribute data of some value, if he will only make notes in a meteorological diary of the most striking atmospheric changes, with the accompanying diseases observed in his practice. Extracts of the most important instances we shall be glad to insert from time to

time in this Journal; and from a collection of such data, obtained from various localities, valuable inductions may be made on surer grounds than could be afforded by the unaided experience of any individual observer. It is a work which especially demands extensive co-operation, such as we trust it will call forth. Such a diary as we have referred to should be kept by every medical man, who wishes to aid the progress of this comparatively new department of medical science; but something more must be done. On looking over such notes, he may be led to suspect that a connexion exists between the changeable weather and the coincident cases of diseases in his district. But these coincidences may have been local and accidental. How shall he discover if they have any sure value as scientific data? Let him occasionally publish a selection of the most striking and accurately observed instances. Let these be compared with the notes of other similar observers in other parts of the country, and the guesses and suspicions may be changed into certainties. The materials which, while lying scattered in the hands of several unconnected observers, might be almost useless, may, when brought together and carefully compared, be found to contain the data for new discoveries in science, and may give to mere opinions and vague suppositions the character of well-founded and important conclusions.

Cui bono? We scarcely anticipate that any well educated medical man would attempt to discourage our labours by this shallow question. It is obvious enough that, if we can attain sound scientific results, they must be associated with practical utility. To give only one example, we shall, at least, be enabled to prescribe more definitely and certainly the prophylactic measures against atmospheric changes, as they affect several diseases. Let us first discover the truth, and we shall be sure to find some good in it.

We reserve for another number several remarks on practical details, the choice of instruments, etc.; but we may observe at present, that all the instruments employed by the observers who will contribute to the weekly reports in this Journal have been compared with standard instruments.

Though we have explained that, hitherto, little has been done for meteorology regarded strictly in its medical aspects, we must not conclude this paper without distinctly referring to the valuable services of Mr. Glaisher, the meteorological superintendent at the Greenwich Observatory. To this gentleman we owe the improvements in instruments and some plans of observations of which we shall make use. Enthusiastic in his favourite science, and possessing rare qualifications for the difficult investigations in which he has for years been engaged, Mr. Glaisher has contributed probably more than any other observer to the increasing popularity of meteorology as a study. The valuable papers published in the *Philosophical Transactions*; the Hygrometrical Tables; the Meteorological Report appended, for some years past, to the Registrar-General's quarterly return of marriages, births, and deaths in England; the observations given with the Registrar-General's weekly return of births and deaths in London;—these are some instances of our obligations to Mr. Glaisher. He was the first to introduce the Dry and Wet Bulb Hygrometer into general use, thus, with the aid of the Hygrometrical Tables, superseding the use of the instrument invented by Daniell, which is too delicate to be generally useful; he has ascertained the corrections to be applied to monthly means of meteorological observations at

any hour; the amount of radiation of heat from the earth, etc., during night; and, in several points of view, has placed us on a vantage-ground at the commencement of our specific study of medico-meteorology. We must not forget to notice here, that Mr. Glaisher is always ready to give valuable information and advice to other less experienced observers.

To Mr. Glaisher we are also indebted for the institution of the British Meteorological Society,* which now includes nearly all the meteorological observers in England, with a considerable number of general lovers of science. These remarks on the great services which have been rendered to science by Mr. Glaisher seem necessary in this place; for, as we have endeavoured to show that, after all, little has been done directly for the object which we now have in view, it is our duty to acknowledge that the advance of general meteorological science during late years, the improvements in instruments, the construction of various tables and publication of observations, extending over some years, are all advantages for which, at the commencement of our special undertaking, we ought to be grateful.

OUR WEEKLY PROGRAMME.

ONE of our leading aims in conducting the Journal has been to make it a faithful exponent of the sentiments of all classes of our fellow associates upon questions of medical polity, science, and practice. We have endeavoured to supply substantial and scientific reading more abundantly than ephemeral discussions; believing that a Journal published under the auspices of an Association, embracing within its pale the ablest physicians and surgeons of this country, ought to take higher ground than the medical newspapers, which, with their "notices to correspondents", their autobiographies, and their "analytical commissions", have obviously a distinct mission of their own. We make this remark from no wish to disparage our weekly cotemporaries, and simply for the purpose of enabling us to state that the reason why we do not imitate them is because we have another destiny. We know that ninety-nine out of every hundred of our readers expect weekly at our hands a substantial contribution towards a library volume of reference, such as we indicated in the following paragraph of our inaugural address:

"We confidently hope to be able to make the Journal what it ought to be—a luminous and practically available epitome of the medical science and literature of the age—such as men of learning and leisure may read with profit and pleasure; and which will supply, in a well digested form, to our more toilsomely occupied majority, all that they have time to peruse, or can conveniently procure." [Jan. 7, p. 2.]

* The British Meteorological Society is under the presidency of Samuel Charles Whitbread, Esq. who, at great expense, has erected an excellent astronomical and meteorological observatory in the garden of his country residence, at Cardington, Bedfordshire. It may be remembered that this spot was the scene of the meteorological researches of the philanthropist, John Howard. The construction of philosophical instruments has been wonderfully improved since the time of Howard! His biographer tells us—"At the bottom of his garden at Cardington, he had placed a thermometer; and as soon as the frosty weather had set in, he used to leave his warm bed at two o'clock every morning, walk in the bitter morning air to his thermometer, examine it by his lamp, and write down its register, which done to his satisfaction, he would coolly betake himself to bed again."—See Hepworth Dixon's *Life of Howard*.

As the Journal is the great bond of union among the members of the Association, we have always reported Association Intelligence at a considerable length, and have likewise given up a good deal of space to the letters of members; but we have yet to discover that this has been either an unprofitable or an unacceptable course of proceeding. We have expressed our own views freely; and therefore, unless we had also given latitude to others to do the same, the Journal would have been perverted from its legitimate use, as the organ of the whole of our body. Regarding gratuitous advice, compulsory vaccination, Sabbath observance, chloroform in midwifery, etc., etc., we have, as in duty bound, stated our own views, as those questions arose before the medical world; but we have also given fair scope to those colleagues who differed from us in opinion. It ought to be obvious to those who grumble at the amount of space which is occasionally occupied by letters, that the Journal is equally the property of all the members of the Association, and that we are bound, as far as possible, to enable those who have something to communicate to their colleagues, to communicate it through the medium of their own Journal.

The daily correspondence which we have with our fellow associates in all parts of the kingdom convinces us that the plan which we published in our first number, under the sanction of the Journal Committee, has given general satisfaction both in its promise and in its performance. We therefore feel no inclination to alter the character of our programme, though we shall steadily strive for ampler resources wherewith to enhance the efficiency of the performance. We regard the introduction of Medical Meteorology into our weekly table of contents as a great step in this direction. This important addition to our original programme has anxiously engaged our attention for many months past, and it has also involved the writing and the reading of some hundreds of letters during that period. We felt that, until the details of our plan were fully matured, we ought not to broach our project, as we knew that the public discussion of the difficulties which we had to encounter was more likely to impede than to facilitate the progress of our arrangements.

An honourable and a lasting renown will belong to the Provincial Medical and Surgical Association, if it be able to maintain the lead which it is about to take in collecting and arranging the facts of a department of science which, though yet in its infancy, has commenced to shed the rays of morning upon fields of pathology which have hitherto been wrapped in clouds of impenetrable darkness. Let the Association be ever animated in this and all its enterprizes by the conviction that, if it make a right use of its great resources, it can do more than any College or Corporation has yet done or can do to give to the medical profession its legitimate and salutary influence in the economics of the state. The Association cannot but be ennobled in the eyes of the world by maintaining a healthful purity of ethics within its pale, and by applying its organization to the elucidation of grand problems in hygienics and pathology which do not admit of being tarnished with even the suspicion of selfishness.

ORIGINAL COMMUNICATIONS.

ON THE TOPICAL TREATMENT OF HOOPING-COUGH.

By EBEN WATSON, A.M., M.D., Professor of the Institutes of Medicine in the Andersonian University, Glasgow.

It is now nearly six years since I began to use topical applications to the pharyngo-laryngeal membrane, in cases of hooping-cough, in the hope of mitigating the paroxysmal spasms of the glottis which form so important a feature of that disease; and, being well satisfied with the results of the treatment, I published an account of it in the *Edinburgh Monthly Journal of Medical Science* for 1849, p. 1287. Seeing, moreover, that no therapeutic measure can be successful, or ought to be adopted, unless it is founded upon a true pathology of the disease for which it is proposed as a remedy, I endeavoured to point out, in the paper referred to, the theory of hooping-cough which commended itself to my mind, and which seemed to me at once to establish the reasonableness of the topical plan of treatment, and to explain the want of success which had attended the employment of general means in cases of that disease.

All experience bears me out in stating that the first and second stages of hooping-cough are marked by catarrhal inflammation of the larynx, trachea, and bronchi. In severe cases, this inflammation involves the whole thickness of the mucous membrane, and may even spread to the minute air-tubes, or to the pulmonary cells, before the spasmodic stage has well commenced. More or less speedily, however, the pharyngeal and bronchial branches of the vagi nerves become involved in the morbid action. It is a common opinion, that this nerve becomes inflamed; but we are not warranted by the results of *post mortem* inspections, nor by any data of "living pathology", in assuming that opinion as proved. At all events, a small amount of inflammatory action, such as may be called irritation, is sufficient to account for the symptoms of the second stage, in which the hoops occur. This feature in the pathology of hooping cough is interestingly proved by Romberg (*Diseases of the Nervous System*, Sydenham Society's edition, vol. i, p. 349), by experiments on the lower animals, performed by himself and others. But probably the cases which happened to Sir Astley Cooper and to M. Gendrin, both shortly stated by Romberg in the passage referred to, may be still more convincing to most minds. They were cases of inflammation, the one of the parotid gland, and the other of an aneurismal sac, in the vicinity of the pneumogastric trunk, and occasioning paroxysms of cough and dyspnoea. To these we might add the cases of small bodies, such as fish bones, etc., sticking about the pharynx, and causing similar symptoms; many of which are now on record.

It would seem, then, to be satisfactorily proved that the morbid agent in cases of hooping-cough commences its operation by producing inflammation of the pharyngeal and bronchial mucous membrane; and secondarily, irritation of the pneumogastric nerves. Now, it is obvious that such cases only differ from ordinary bronchitis, so far as their mechanism is concerned, in the amount of irritation produced in the pneumogastric nerves. In ordinary bronchitis, this is nothing more than what will suffice to produce those expulsive efforts in which coughing consists; while in hooping-cough it is so great as to excite again and again a spasmodic closure of the glottis, which at once prevents the expulsion of the offending mucus, and so impedes inspiration as to occasion the well known crowing sound that accompanies the act. In this stage, the stomach likewise becomes affected, and vomiting is a common termination of a fit of coughing; but this is easily explained on the acknowledged truths of physiology—the irritation of one set of branches, or of the trunk of a nerve, is capable of producing action in organs supplied by the same

having a common centre, and, *à fortiori*, by other branches of the same nerve-trunk.

Two questions are yet necessary to be considered, in order to complete a theory of whooping-cough. These are: first, In what relation does it stand to its so called complications? and second, What is the nature of the agency which starts the train of morbid effects of which we have been treating?

There would be little need of remark on the first of these points, were it not that almost all its attendant symptoms have been considered as part of the disease, and not as complications at all. It is indeed difficult to draw the line of demarcation between the bronchial inflammation which is essential, and that which is accidental to the whooping-cough; but, as we have certain well marked cases of the latter, in which the former state is either absent, or confined to the pharyngo-laryngeal membrane, I think it fair to consider all inflammatory action beyond that as complicating the primary disease. The same, in my opinion, is true of inflammation of the air-cells, and still more so of those complications which cannot be considered as extensions of the primary effect of the morbid agent. I refer to cerebral and abdominal complications, to dilated bronchi or ruptured vessels, all which may be traced, more or less directly, to the violence of the paroxysms of dyspnoea.

On the second point, I have only to remark, that the almost invariable occurrence of whooping cough, once in the life of every person exposed to its influence, its exhausting his susceptibility to suffer from it in the first attack, and its undoubted communicability from one patient to another, in the same manner as other diseases which are usually considered infectious or contagious, warrant the common belief that the disease is due to the operation of a morbid poison in the blood, the effects of which are manifested in the manner formerly explained. This poison seems to circulate in the system for a time before producing decided symptoms of the disease. About eight days usually elapse, during which the patient is affected with fever and other symptoms of common catarrh, before the stage of whooping commences at all. But as soon as the spasmodic stage is fairly established, all the symptoms of general disorder in most cases subside; and, unless some complication occur, the disease remains, during its future course, a local affection of the larynx and bronchi, without any evidence of a morbid condition of the circulating fluid. I think it more than likely, then, that the poison of whooping-cough is generally eliminated or rendered innocuous by the time that the spasmodic stage of the disease has reached its acme.

The objection, then, which I have heard urged against the topical treatment of whooping-cough, viz., that it does not aim at neutralising the morbid poison which originated the disease, but only at removing or mitigating the local effects thereby produced, must lose its point, if the facts just alluded to be admitted; and I believe few will doubt them, who have had much experience of the disease; for these facts prove that the whooping-cough is, for a long period of its course, the evidence rather that a peculiar morbid poison *has been* than that it *is then* present in the blood; and if it be remembered that it is in this very period that complications are most apt to arise and to endanger the life of the patient, the importance of checking the progress and counteracting the results of the morbid poison will not be denied, even though the measure by which this is to be accomplished lays no claim to the doubtful title of a hæmatic or blood medicine. For it ought not to be forgotten, that we have no very satisfactory proof that any of the remedies in use for other zymotic diseases act as direct antidotes to the morbid poisons which originated them. The action of quinine in cases of intermittent fever is by no means so uniform or certain as we should expect in an antidote to the paludal poison; while at least one other substance of a totally different nature, viz. arsenic, has produced results almost, if not quite as favourable. And besides, many other therapeutic agents, evidently acting upon the local and secondary effects of the poison, such as bleeding, mercury, etc., nearly approach, in their curative influence

upon the disease, those which are usually considered the more direct and antidotal remedies. The prevention of small-pox by vaccination is hardly a case in point; because it is merely an instance of one morbid poison exhausting from the blood the substance on which the other poison acts. It must therefore be confessed that we at present know little either of the nature or *modus operandi* of the morbid poisons, and perhaps even less of the antidotes that may be capable of counteracting them in the blood. While, then, we eagerly seek for the elements of induction regarding zymotic diseases; nay, while we admire the beauty of Liebig's fermentation theory of their origin, so ably supported by Dr. Carpenter in a recent number of the *Medico-Chirurgical Review* (No. xxi, p. 159), still it is useless to dream of founding, *as yet*, any rational system of therapeutics on such imperfect though beautiful hypotheses.

If, then, we cannot at present hope to be able to treat zymotic diseases by remedies aimed at neutralising the morbid poisons which remotely excite them, the only reasonable plan of dealing with them is to shorten or cure the secondary effects of these primary agents. To take the case of whooping-cough; we do not yet know of any medicinal substance that deserves to be called an antidote to the poison which at first excites the disease. We have, however, learned by observation that it produces two secondary diseases; viz., inflammation of the mucous membrane of the air-passages, and next, irritation of the vagi nerves. While then we have no means of treating, with any hope of success, the remote cause of these morbid states, we can, with almost certain success, treat the latter; and having cured them, it is matter of experience that the poison becomes speedily eliminated, and does not reproduce itself. I consider this a sufficient defence of the topical treatment against the objections of those who would have us, in fact, cease to treat zymotic diseases until we discover antidotes to their remote causes.

Let us now consider shortly in what way the solution of caustic, applied to the interior of the pharynx and larynx, acts in curing the local effects of the poison of whooping-cough. M. Joubert seems to think that the topical remedy only affects the inflammatory state of the mucous membrane, and the excessive secretion of mucus which results therefrom, and to which he attributes the spasmodic element of the disease. I have not been able to see his memoir, which is published in the *Recueil des Travaux de la Société Médicale de l'Indre et Loire*, 1er et 2de trimestre de 1851: but the following passage sufficiently indicates his opinion. "M. Joubert n'a pas, du reste, été conduit à employer ce traitement dans la coqueluche par le désir de modifier l'élément spasmodique en agissant sur les nerfs qui se distribuent aux voies respiratoires, mais seulement par l'idée théorique de modifier la disposition en vertu de laquelle s'opère la sécrétion morbide, à la présence de laquelle il attribue la toux convulsive." (*Bulletin Général de Thérapeutique*, tome xlii, p. 41.) Now, as the only disposition in the mucous membrane which determines the secretion is its inflammatory excitement, so it is upon that alone that M. Joubert considers the topical remedy to act. Nor do I seek to dispute the fact that such an action is effected, nay, that it is *first* effected in every case of whooping-cough in which the topical treatment is employed. But if the case be well watched, it will be found that, after the inflammation of the pharyngo-laryngeal mucous membrane is subdued, and after the expectoration has diminished in amount and in bulk, the whoops continue, though, in general, they are less frequent and less severe. In most cases, the remedy must yet be continued for a short time before the cure can be accounted complete. When, however, the inflammation of the larynx or trachea happens in any case to be peculiarly severe, the cure by topical means is always postponed for a longer time than usual; and this would seem to show that the nervous or spasmodic element seldom gives way before the inflammatory.

Not long ago, I treated two children in the same family, who were attacked at the same time by the whooping-cough. The one was a baby at the breast, and was very severely

affected, inasmuch that his life was for a time in danger. I began the topical treatment about the middle of the spasmodic stage; and in eight days he had ceased to hoop, and in a short time, to cough at all. His sister, the other patient, was about two years and a half old, and apparently much less severely affected with the hooping-cough; but she had just recovered from an attack of croup when she was seized with that disease, and at first her cough had much of the croupy sound. I treated her *pari passu* with her brother; and yet her disease continued two weeks longer than his.

On the other hand, I have known of cases irregularly treated by the topical method, in which the inflammatory element was subdued, and in which the hooping continued, though in a mild degree, for a considerable time longer. But the most convincing proof that the solution of caustic has a decided and sedative influence on the spasmodic element of hooping-cough, or, in other words, on the excited state of the extreme branches of the vagi nerves in the throat and larynx, is the fact, which my experience demonstrates, that the topical plan is most speedily effectual in the last stage of the disease, when all the previous symptoms of inflammation have disappeared, and the hoop alone remains. I have seen a number of such cases, in which the children seemed worn out by the disease, and in which general remedies had been long but vainly employed. In all these cases, the very first touch has a markedly beneficial effect; and its repetition for a comparatively few times suffices to perfect a cure.

When, however, we remember how much the nerves of any part are implicated in its inflammation, it may be, after all, that the affection of the pharyngeal and bronchial nerves, which occasions the spasmodic paroxysms of hooping cough, is of the same nature; and that we are warranted in agreeing in the main with M. Joubert, that the topical application of solution of caustic operates solely in subduing inflammation. Since, then, that morbid state exists in the bronchial mucous membrane as constantly in cases of spasmodic asthma* as in those of hooping cough, the rationale of the topical remedy becomes reduced to the counter action of only one morbid state; and we may call it an antiphlogistic sedative of the pharyngo-laryngeal mucous membrane. But this, in my opinion, can only be said with truth of the less sthenic degrees of inflammation, as I have explained in another paper (*Dublin Quarterly Journal of Medicine*, August 1852). The practical rule, however, remains importantly true, that the remedy should be continued so long as the slightest hoop is heard, although all the ordinary symptoms of inflammatory action, such as bronchitic rales or bulky expectoration, have been subdued for some time. If this rule is not strictly attended to, a relapse will ere long be the consequence; and the treatment will have to be continued nearly as long as if it had never been commenced at all. But if the disease be thus thoroughly subdued in its first attack, no recurrence of it need be apprehended during the patient's life. I make this statement in full knowledge of the succeeding history of all the cases in which I have employed the topical treatment; and many of them have been again freely exposed to infection.

Regarding the mode of prosecuting this topical treatment, I may now be allowed to make a few remarks, suggested by the statements or objections of other physicians, which I have either read or heard expressed in conversation.

1. The most convenient instrument for applying any solution to the throat or larynx, is the sponge and whalebone. The forceps suggested by Dr. Cotton, and which has one limb covered with sponge, is needlessly complicated, and much more apt to injure the delicate glottis. Nor is it fitted to obviate the supposed danger of the detachment of the sponge in the windpipe of the patient, which gave rise to the idea of Dr. Cotton's instrument at the first. It is, indeed, quite a mistake to think that there is any strain upon the sponge, when once it is within the

larynx. That organ cannot contract so as to detain the sponge; and it must have been very carelessly fixed on the whalebone, if the glottis could detach it during its withdrawal. Indeed, a skilful operator will seldom feel the contraction of the glottis at all; for, as the patient inspires immediately on the introduction of the sponge into the larynx, the muscular valve becomes relaxed and permits its easy withdrawal. The strong contraction which I have myself often felt, and which I have known many to mistake for that of the glottis, is in reality a proof that the sponge is not in the windpipe at all, but is caught by the pharynx immediately behind it. And this gives colour to the amusing story of the musician, whose larynx was being touched by a learned physician, who, on withdrawing the whalebone, found it destitute of the sponge. The physician was in great alarm; but the patient neither choked nor died. Ere long, however, he vomited the sponge from his stomach. It had been caught by the pharynx, and swallowed.

If the instrument is at all well made, this could never happen, except from one circumstance, which ought to be known by every person who attempts the topical treatment of the larynx, especially among children. It is, that the caustic solution in a short time destroys the thread with which the sponge is fastened to the whalebone. The simple and certain way, then, of avoiding any such accident as that to which I have been referring, is to have the sponge frequently renewed.

2. It would appear, from the following passage, that M. Joubert supposes me to have recommended the indiscriminate employment of a solution of the nitrate of silver of uniform strength: "Il n'y a pas une grande différence entre le procédé opératoire suivi par M. Joubert et celui de M. Watson; seulement le premier emploie des solutions concentrées à des degrés différents, depuis 1 gramme jusqu'à 4 grammes de nitrate d'argent pour 30 grammes d'eau distillée, et qu'il désigne par les numéros 1, 2, 3, 4." (*Bulletin de Thérapeutique*, tom. xlii, p. 41.) Now, saving the designation of the solutions by the numerals 1, 2, 3, and 4, which is doubtless a convenient plan when employing them on a large scale, there is no novelty in this practice of M. Joubert. For in my original paper on the hooping cough (*Edinburgh Monthly Journal*, Dec. 1849), I distinctly state that "the ordinary strength of the solution which I have used in the treatment of hooping cough, is gr. xv of the nitrate of silver to the ounce of distilled water; but, in some cases, I have with advantage increased it to ʒij of the salt in the ounce of water." From an enlarged experience of the treatment in question, I can now be still more precise; for I have found that in the early stage of the disease, and just in proportion to the intensity of the inflammatory process which may be present, so ought the solution employed to be proportionally weak. Afterwards, when the nervous symptoms predominate, the solution may with advantage be strengthened; but it is impossible to lay down rules that will universally apply to different cases, or even to the same case on different days. This must be left to the judgment of the practitioner; and he will find it quite necessary, for the favourable progress of the case, that he should use his discretion in regard to it, as much as to the administration of emetics or laxatives.

3. Dr. Scott Alison has lately drawn the attention of the profession to the application of several other substances to the larynx; and perhaps some of them, such as solution of morphia, may be occasionally used with advantage in cases of hooping-cough. I merely make this as a suggestion; but I have, from some little experience of its effects, a better founded opinion of another substance, which has not hitherto, I believe, been used as a topical application to the larynx. I refer to the hyposulphite of soda and silver, to which my attention was first directed by a notice in the *Medico-Chirurgical Review* (No. xxii, p. 567). This salt has a very soothing effect on the larynx when its lining membrane is irritated by a vitiated, and, as is generally the case, an acid secretion; and I entertain the hope that its solution will form a useful topical application in the first stages of hooping-cough. I intend, however, some time to lay before the profession a fuller account of its

* I have recommended the topical treatment of the larynx in cases of spasmodic asthma, in another paper: See *Glasgow Medical Journal*, No. 1, p. 37; and the *Periodic Review of the Association Medical Journal*, No. xxi, p. 462.

which I am at present making, of the value of this salt in laryngeal cases.

4. In some cases of whooping-cough, an obstacle is presented to the topical treatment, by a state of matters which is, in other respects, by no means unfavourable to the patient. I mean the irritability of his stomach, which makes the slightest touch of the sponge in the throat the signal for violent retching and vomiting, if the stomach be full. I very often, therefore, find it necessary to prescribe for this symptom frequent small doses of heavy magnesia, combined sometimes with a few grains of the trisulphate of bismuth. Such simple treatment seldom fails to mitigate the vomiting sufficiently to admit of the continuance of the topical applications.

5. These applications should be renewed at least every second day; but, if their commencement has been delayed till the disease is at its height, or if the whoops are very violent from the first, they should be repeated more frequently: and, for the reason stated above, the time of making them should be selected so as to have the stomach empty; and the patient should not be allowed to eat for an hour or two afterwards, else the feeling of rawness in the throat, which follows each application of the remedy, will be unnecessarily increased, and occasionally whooping and vomiting will be induced.

6. In making these applications of solution of caustic to the throats of children, everything in the shape of a formidable spatula should be dispensed with, and either a common teaspoon, or the index-finger of the left hand, should be used. In all cases in which it is important to pass the sponge into the larynx, I consider it quite necessary to introduce the finger into the patient's mouth, and to touch with it the tip of the epiglottis, along the surface of which the instrument may be glided down with certainty to the rima glottidis. And if this proceeding be performed at once with firmness, few children either can or will resist it by struggling, or by biting the operator's finger; but much patience and tact is sometimes necessary to school them to submission in the beginning of the treatment. After a few times, no more trouble is experienced.

Pursued in this way, with these precautions, and with a prudent attention to the diet and regimen of the patients, the topical treatment of whooping-cough wonderfully shortens the disease, and renders it nearly as mild as ordinary catarrh. Complications seldom occur, and thus the disease is stripped of its most formidable characteristic. Hence it is that I can give the following favourable numerical account of the results of the treatment in question.

	Cured within a fortnight.	Cured in 3-4 wks. treatment.	Resisted	Total
M. Joubert's cases	40	20	8	68
Cases treated through- out by myself	46	20	8	66
	86	40	8	134

In contrast with this table, I subjoin another of the ordinary duration of the disease when treated in the usual manner, as stated by a few of our best and most recent authorities.

Dr. R. Williams* states it at from 2 to 4 months, or more than a year.

Dr. Copland† states it at from 32 days to 5 months, or more.

Dr. C. J. B. Williams‡ states it at from 6 to 10 weeks, or more.

Dr. Walsh§ states it at from 8 to 13 weeks, or more.

Dr. West|| states it at from 8 to 14 weeks, or more.

MM. Barthez et Billiet¶ state it at from 1 to 3 months, or more.

Average of all the statements from 1½ to 3½ months.

* Williams on Morbid Poisons, vol. i, p. 311.

|| Lectures on Diseases of Children, p. 272.

¶ Traité Pratique et Clinique des Maladies des Enfants, 2me édition, tom. ii, p. 694.

I think it right to add to the above computations, the following statement of Dr. Robert Watt, whose treatise on the chin-cough, though published in 1813, may still be consulted with advantage, especially in regard of the history of the disease. "Nothing," he writes, "can be more uncertain than the course and event of this disease. In the mildest form in which it appears, it usually continues for two, three, or four months; in the more severe, it may last twice, or even thrice as long." (*Treatise on the Nature, History, and Treatment of Chin-Cough*. Glasgow, 1813, page 69.)

I have no ready means of shewing the proportion of deaths to attacks in this disease; but no one can dispute that it is a very considerable cause of the enormous mortality occurring among young children in this country. According to the reports of the Registrar-General, the deaths from whooping-cough in London stand in the proportion of 8.9 per cent. among females, and 6.2 per cent. among males, to the deaths from all causes under ten years of age. And in Glasgow, the proportion is nearly the same; the deaths from whooping-cough being 8.7 per cent. of the deaths from all causes under ten years of age.

Surely, then, a treatment which promised to diminish, or, perhaps, to annihilate, this very great mortality, ought to have been received with consideration by the profession. Such, however, has not been the case in the present instance: for, though such a promise has not only been given by it, but rendered almost certain by the results of an extensive trial, yet such a reception has not been accorded to the topical plan of treating the whooping-cough; at least if I may judge from the circumstance that few or none of our recent writers on children's complaints have noticed, far less recommended, the plan. Thus Dr. West, though he confesses that there is nothing "unreasonable in the expectation that a remedy (for whooping-cough) may some day or other be discovered which shall cut short its course with as much certainty as quinine arrests an intermittent fever, or which shall render the constitution insusceptible of its poison as infallibly as chicken-pox (cow-pox) preserves from variola;" yet he adds, "at present no such remedy has been discovered; and though the severity of an attack of whooping-cough, or its duration, varies greatly in different individuals, during different epidemics, and at different seasons of the year, yet we are unable, by any medicinal agents, to produce effects such as in these cases flow from causes quite beyond our control."* But surely the numerical results just given prove in a manner beyond all cavil, that the simple treatment which I have suggested is capable of cutting short the whooping-cough with as much certainty as quinine arrests an intermittent fever; and moreover, that it renders the disease, while it lasts, both milder in type and safer to the patient than the most favourable circumstances of season or epidemic could possibly do. For it should be borne in mind, that the results alluded to have been obtained at different seasons of the year, in different countries, during different epidemics, and by different observers. Seldom, indeed, has any new remedy so well stood the test of such a varied and extensive trial. At the same time, I hope that the theoretical considerations which I have stated so fully, and which are the general expressions of so many individual facts, sifted and weighed according to the strictest method of induction, remove the topical treatment of whooping-cough from among the vague class of *specifics*, and place it among the agents of rational medicine.

In contrast with the disregard, which is indicated by the silence of English physicians, as to the topical treatment of whooping-cough, I could quote the favourable opinions of many continental writers. For example, not only has M. Joubert put the treatment to the test of an extensive trial, but Dr. Debaud, in giving an account of it, alludes to his own experience in the following terms:—"Nous avons eu depuis, nous-mêmes, l'occasion de vérifier les effets favorables de cette pratique dans plusieurs cas de cette maladie."

* West on Diseases of Children, p. 208. Second edition: 1868.

(*Bulletin de Thérapeutique*, tome XLII, p. 41.) And in the recent edition of the elaborate treatise of MM. Barthez et Rilliet, the topical treatment of hooping-cough obtains a place amongst the available remedies for the disease. I shall be excused for quoting their brief but sufficient description of the method:—"Le Docteur Watson a conseillé l'emploi de la cautérisation pharyngo-laryngée avec une solution de nitrate d'argent de 75 centigrammes à 2 grammes 40 centigrammes pour 30 gr. d'eau distillée. M. Watson se sert d'une éponge solidement fixée à une baigne accourbée; la tête du malade étant fixée par une aide, et la langue préalablement abaissée, il porte l'éponge jusqu'à l'ouverture de la glotte; il résulte de cette petite opération une sensation de suffocation très légère et temporaire que l'enfant a bientôt oublié." (*Traité Clinique et Pratique des Maladies des Enfants*, 2me édition, tom. II, p. 657, published in 1853.)

I hope, then, that it may not be utopian to expect that the day is not distant when the treatment, so well described by these excellent writers, and the usefulness of which I have now been enabled to establish, very mainly, through the generous zeal and untiring perseverance of another French physician, will be more favourably received in this country, and more generally adopted by British practitioners of medicine. Were such to be the case, I do not doubt that the result would be displayed in a marked diminution of mortality among children, and in the removal of a long-standing opprobrium to the healing art.

Glasgow, August 1855.

ON CHOLERA, AND ITS TREATMENT BY COLD WATER AFFUSION OR DOUCHE.

By E. M. MACPHERSON, Esq., late Surgeon in the Army.

HAVING had various opportunities of treating cholera, during a service of nine years in India, and of testing the efficacy of cold water affusion in many cases of the worst description, since June 1845, I believe that a report upon this mode of treatment, which has been found so immediate in its effects, and beneficial in its results, will merit attention. And, if conclusions may be drawn from the ostensible principle of its action, the real nature of cholera cannot fail to be more distinctly recognised than has yet been acknowledged.

Before entering upon this report, it may be advisable, for the elucidation of the subject, to glance at the difference supposed to exist between cholera in Europe and cholera in Asia; and, for the better appreciation of the treatment proposed, to determine, from the copious and accurate data recorded of cholera, what is the leading characteristic of the disease, and what ought to be the object of our treatment in regard to it.

That the difference supposed to exist between the Asiatic and European forms of cholera is one of degree only, not of kind, will be evident on a cursory inquiry. Hence it will also be evident that the treatment applicable in the one form, is equally so in the other. In Asia, where the disease may be said to be indigenous, cholera, true to its history, bursts forth in all its vigour, and from the first appears in its advanced stage, or stage of collapse—in this country denominated its second stage. But when, after its onset in this advanced stage, it subsides in the virulence of its attacks, and the cases become milder, more amenable to treatment, and less rapidly fatal, it will be found to assume that form of the disease in which vomiting, purging, and cramps, prevail, and to be in every respect identical with the so-called European cholera.

In Europe, on the other hand, where the disease is almost invariably ushered in by vomiting, purging, and cramps, these symptoms constitute its first stage; but when these symptoms have ceased, and when, as dissolution approaches, the first has passed into the second stage, or stage of collapse, cholera in Europe will be found identical with cholera in Asia, where so many are struck down almost lifeless from the first.

How far these symptoms, viz. the vomiting, purging, and cramps (upon which so much stress has been laid in the pathology and treatment of the disease), ought to be taken into account, the known history of cholera in all places, and under all circumstances in which it has shown itself, will satisfactorily decide.

If the value of a symptom, with a view to treatment, is to be regarded in proportion to its influence on the fatality of a disease, then neither the vomiting, nor purging, nor cramps, will be found worthy of any consideration whatever in the treatment of cholera.

In the words of Dr. Copland, in his treatise on cholera: "The vomiting and purging, which are far from being the most dangerous symptoms, and are often the most remarkable in the least urgent cases, are generally slight, or at least not profuse, in those attacks where the sinking of the vital energies is the most rapid and greatest, and are readily allayed by medicines. The spasms are often slight, or nearly absent, in some of the most rapidly fatal cases."

That these remarks are fully borne out by the history of the disease, all who enter into the subject, and extend their observations beyond their own doors, may satisfy themselves. They may also infer, what must be obvious to most who have had experience of cholera in India, that the symptoms in question,—the vomiting, purging, and cramps,—if at all constant in their relation to the disease, seem to be so in an inverse ratio, as in compression of the brain, to the depression of vital energy. In other words, the collapse or asphyxia, which, with its sequelæ, oppressed respiration, impeded circulation, coldness, blueness, etc., is the only invariable symptom, and therefore the leading characteristic of cholera, and ought to be the object of our treatment; not only because it is the only constant symptom, but also, perhaps, rather, on the proof which experience will give all who have treated cholera, that reaction is the forerunner of every amelioration in the symptoms during an attack, and the only sign to be depended upon in forming a prognosis. It was in producing this reaction that the cold water effusion or douche was found so beneficial.

At Cawnpore, in June 1845, cholera broke out in the 53rd regiment, to which I then belonged, with the same virulence as attended it in various localities throughout India during that and the succeeding year. Two men, the last survivors of several who had been attacked within two days, were sinking under that fatal collapse which alone, without any other symptoms, marked all the cases that had occurred in the regiment.

Every remedy that could be devised to produce reaction had been tried in vain; they might as well have been put into the patients' breeches pockets, or applied to the bed-post. The exhibition of the nitrous oxide gas was not only fruitless, but far from encouraging. The breathing under its use became more oppressed and hurried; there was no pulse, nor was it rendered perceptible by the gas; and, as its continued exhibition distressed the patient, it was thrown aside as worse than useless. In despair at the utter want of the most trivial effect from the remedies employed, I made trial of the cold water affusion. I desired the water-carrier to pour water from his leathern bag over one of the patients; and, as the effect was good, then over the other patient, placed naked on a bedstead in the verandah. Attendants were at the same time employed in rubbing the limbs and trunk with their palms, and afterwards with dry towels. A refreshing sensation and comparative reanimation having followed each repetition of this operation, it was had recourse to at intervals, though only with the success of having prolonged life, which was ebbing fast for some hours.

This success, poor though it was, seemed to warrant the conclusion that, had the remedy been applied while somewhat more of life remained, recovery might have been the result. To test this conclusion by experiment, an opportunity was not long wanting.

On the same evening, as if by some fatal blast sent over the barracks, several men were suddenly struck in a state of collapse. Some retained consciousness, and

asphyxia); a few lost it, and were in a state of complete coma (*apoplexia*), with stertorous breathing; in three cases, attended with convulsions; others, especially towards morning, and during the two following days, were affected by vomiting, cramps, purging with rice-water dejection, and the usual concomitants of cholera in Europe.

How many came under treatment at this time, I cannot now venture to affirm; but I believe I am correct in stating that, of all admitted, but two died—one of apoplexy; the other, who was allowed a warm bath, of cholera. The rest, all of whom recovered from the cholera, were treated by the cold water affusion.

Since the period above alluded to, I have not had an opportunity of treating cases of epidemic cholera. Several cases, however, of endemic cholera among Europeans, while it was, as often happens, epidemic among the natives, have been treated by me in every instance with success.

One of the most remarkable of these endemic cases occurred at Meerut, in August 1848. A corporal of the 9th Lancers, an atrabilious subject, was brought to hospital at 4 P.M., almost pulseless, having been purged during the morning, and having passed several rice-water dejections on admission into hospital. There were slight cramps, and occasional efforts to vomit. He was immediately placed in a hip-bath, and water was poured over him, while hospital attendants rubbed the limbs and trunk. This was continued until he became chilly, and shivered. He was then removed from the bath, dry rubbed, and placed in bed, much revived by the operation, as was shown by less oppression in breathing, and a more distinct pulse. After remaining in bed for about half an hour, he began to relapse; the pulse sank; vomiting, purging of rice water, and cramps, returned. He was replaced in the bath, with the same effect as before. Being again placed in bed, he again relapsed. The water was again had recourse to, and repeated at intervals as above, according to symptoms, until 10 P.M., six hours after its first application. The respiration then became free, the pulse soft and distinct; the natural warmth was restored, and remained; and the patient slept until morning, when he awoke with a furred tongue, feeling weak and drowsy, but without that consecutive fever so often more fatal than the disease itself, and which has always seemed to me to follow most in those cases in which brandy, opium, ammonia, or other stimulants, have been freely administered.

Meagre and unsatisfactory as the above statements must appear, taken as evidence of the efficacy of the treatment advocated, yet, if the action of the remedy shall be thought to afford a satisfactory explanation of its curative effect, one case successfully treated in the manner prescribed will carry more weight than accurate details of numerous cases, treated by the unknown action of some occult remedy.

The first effect of cold water, poured over the head and chest in a small stream from a water ewer, held at a greater or less height by a person standing on a chair or raising his arm over the patient placed in a bath while frictions are applied to the trunk and limbs, is to produce, as in cases of ordinary asphyxia, a convulsive gasp or forced inspiration, succeeded by two or three strokes of quickened respiration. With each gasp, as by a convulsive throe, the parietes of the thorax, before immovable, will be observed to expand, and the diaphragm will descend. Simultaneously with each effort of inspiration, the impeded circulation will be found to flow, the pulse to partake of the impulse, and the sluggish pupil to resume its wonted sensibility. These are the first and immediate effects of the water douche. When continued, they constitute reaction; and if this is maintained, the vital energy, even at its last ebb, the natural heat of the surface, and the colour of the skin will be restored. This is effected by the imbibition into the blood, through respiration, of atmospheric air taken in at each forced inspiration; the entire surface being at the same time stimulated by frictions to the limbs. It being evident, according to this view, that the stimulating effect of the cold water douche is to be attributed to its power of exciting the respiratory function to take oxygen into the system, it may be inquired how the

experiment with the nitrous oxide gas above alluded to failed so signally. One essential condition to its action was wanting; viz., that expansion of the thorax for the reception of air into the lungs, upon which the effect of the water douche so much depends. Since I have become aware of this as an essential condition in the effect produced by the water douche, I have not had an opportunity of repeating it in conjunction with the gas; but may it not be presumed that, taken together, if they do not prove an antidote to the disease, they are at least worthy of a trial. That the want of oxygen in the blood is the cause of cholera, has often been advanced, if not generally admitted; but the effect of this want upon the brain in producing vital depression seems to have been overlooked; while its effect, or that of some poisonous miasm in the system, upon almost every other organ of the body, has been fully insisted upon as indicative of some particular line of treatment to be pursued.

How symptoms are to be regarded as indicative of treatment has already been noticed. Is it not, however, a general law of the system that any violent shock inflicted upon it, as in concussion, compression, some cases of poisoning, and in cholera itself, is followed by vomiting, purging, cramps, and suppression of urine, in a greater or less degree according to the nature of the shock, unless vitality shall have been so overwhelmed by the force of the injury as to pass away without any attendant symptoms, save suppression of urine, which being in proportion to the collapse, gives, by its cessation, one of the surest indications that a generous reaction has set in?

In cholera, as in cases of drowning or poisoning by carbonic acid gas, in all of which the *post mortem* appearances are so strikingly similar, may not suspended animation, collapse, or asphyxia, be ascribed to the paralyzing effects of carbonized blood upon the brain? For, precisely in proportion to the removal of this effect by the stimulating agency of oxygen imbibed through the respiration, will reaction ensue, and the powers of life return, and all the symptoms that characterised the affection disappear. The mode of using the cold water affusion has been pointed out in the case detailed as having been under its operation for six hours. The most essential requisite for the successful application of this mode of treatment was found to be undaunted perseverance, so long as after each relapse reaction could be induced by its repetition. It was a want of a knowledge of the good effect of this perseverance, that caused those two cases first mentioned to be given up in despair. Each time that the douche was resorted to, its effect was of longer duration; until at length, by watching and perseverance, the respiration, "the pendulum of life," was set in motion; every part of the vital machine dependent upon it moved in concert, and the brain, the main-spring of life, was restored to its wonted power of maintaining the just equilibrium.

With respect to the state of the atmosphere during the time that cholera prevails, much has been said. One simple fact, familiar to many, I would mention, as I have not seen it alluded to before; the dimness of lights, and the dulness of fires in cholera seasons, are as striking as their brightness and briskness in this country in frosty weather. If the presence of oxygen is allowed to be the cause of the latter, the former may be imputed to its absence; and the opposite states of feeling in all animated nature, induced upon those who have experienced both, is beyond question.

The mode of applying the cold water douche merely consists in placing the patient in any convenient position, so that, while water is being poured over him, frictions may be applied to the limbs. After the gasping has ceased, this process is to be continued until the depressing effect of cold, shivering, and chattering, sets in, when the pulse will begin to fall. The patient is then to be placed in bed, having been well rubbed. In a short time, when warmth begins to return, relapse will take place. The water is to be repeated in the same manner as above, and persevered in so often as collapse recurs. After each repetition, its effect will be found to be more palpable and more pro-

longed; until at length, through the agency of the imbibed oxygen, the system is restored to its wonted power.

Many have mentioned in a general way the good effect of cold water in cholera; but none, I think, have understood the reason of this good effect, and therefore it has not been carried to its full extent.

It may be well to add, for the satisfaction of those who cling to the idea that cholera is a disease of vomiting, purging, and cramps, that under the water treatment, as described, these symptoms will soon cease to be objects of attention. They will in general subside on the first application, and seldom reappear after the third or fourth.

As to internal remedies, water to drink freely will be found the most agreeable to the patient's taste, less productive of nausea and depression, and not so prone to give rise to the often fatal consecutive fever.

As to the premonitory diarrhoea, on which much stress is laid, I would remark that in the worst cases of cholera it neither precedes nor accompanies the disease; that often, where it subsides, cholera sets in; that where it continues, cholera does not necessarily follow; that it is not part and parcel of the disease; that to view it as such, and to treat it accordingly, can only be in accordance with that style of medical reasoning which has ever puzzled the profoundest lawyers.

August 1853.

PERISCOPIC REVIEW.

SURGERY.

CASES OF CHRONIC INFLAMMATION OF THE KNEE-JOINT.

The following cases are reported in the *Lancet* for June 4th and 11th.

CASE I. Thomas T., aged 8½ years, a scrofulous looking child, was admitted into Isaac's ward, in St. Thomas's Hospital, under Mr. South, on September 23rd, 1851. The patient had been ailing from infancy, and was attacked about three years previous to admission with severe pain in the knee-joint. This acute inflammation subsided after a little while; a twelvemonth passed with comparative ease, when the pain returned, and the child entered Guy's Hospital, where he remained fifteen weeks, and then repaired to St. Thomas's. On examination, the knee was considerably swollen, the pain not very severe, but the boy complained when pressure was made on the patella. There was much swelling and fluctuation above the inner condyle, and between the ham-string muscles, and also on both sides of the head of the tibia. The leg could be moved without assistance or pain, and the child did not recollect having struck the knee, or received a blow upon it.

Emollient applications and rest were ordered. The swelling gradually increased for the next three weeks; and in about six, the matter came to the surface, and pointed. An opening was made in a bulging part below the knee, and about four ounces of thin whey-like matter were evacuated. The boy's health kept up pretty well, but the discharge weakened him. Five months after admission, four sinuses had formed around, above, and below the knee; they all discharged thick purulent matter, of laudable colour and consistence. The ends of the bone seemed somewhat enlarged, the leg was flexed on the thigh, and the boy's health was declining, although he had been kept on nutritious diet.

Five months after admission, amputation was performed, whilst the patient was under the influence of chloroform. Very little blood was lost, but the boy vomited several times during the operation. There were found thickening of the synovial membrane, absorption of cartilages, and caries of bone.

CASE II. A. B., aged 15 years, a strumous girl, but in tolerable general health, stated that her left knee had been in a morbid condition for twelve years. Enlargement and inflammation of the joint were supposed to follow an injury with which the patient met when only three years old. Rest and the usual mode of treatment enabled her after some time to move about on crutches; but she remained liable to attacks of inflammation, which necessitated rest and confinement to bed.

It was after a fall, and a consequent injury to the joint, that

Mr. BIRKETT first saw this patient in Guy's Hospital in the summer of 1852: the joint was then almost fixed, but allowed slight flexion, which gave great pain; the patella was immovable, and the tibia drawn backwards on the femur. After the patient had been kept at rest for about two months, the inflammatory action subsided, but again commenced as soon as movement of the joint was permitted.

The girl now became quite worn out, and wearied by the idea of confinement to the horizontal posture. At her earnest entreaty, the limb was amputated on 21st September 1852.

On examination of the joint, the cartilages could no longer be seen; isolated points of inflammation, with a little pus here and there, were observed; and some vascular fringe-like fibrous formations were in contact with the bones, which were soft and spongy, and contained much adipose matter.

CASE III. William B., aged 14 years, was admitted into St. Bartholomew's Hospital, September 14th, 1852, under the care of Mr. STANLEY. He had been employed at saw-mills, had generally enjoyed good health, and stated that, while working one day, a boy darted a piece of pointed wood at him, which entered the flesh at the knee. He withdrew it; the wound bled very little, but the pain was so great that he was obliged to leave his work and go home (about five minutes' walk). His mother bathed the part with warm water and applied a poultice. This treatment was continued for ten days, but the swelling increasing, the patient was brought to the hospital.

On examination, Mr. Wormald considered that fluid was effused in the joint, and he made an incision over the articulation, but not into it. Purgatives and a spirit lotion were ordered. The swelling at first diminished, but it increased in a few days, and pain towards the inner part of the thigh was complained of. The leg was now put into a splint-box, small doses of mercury were prescribed, and twelve leeches applied to the joint. As no improvement took place, the leeches were repeated. Two days after this, an indurated and painful spot was noticed on the thigh. Leeches relieved the pain, but the boy was becoming emaciated, and signs of hectic fever appeared.

One month after admission, an opening occurred spontaneously on the external part of the knee; much pus escaped, and pressure on various parts of the joint caused purulent matter and blood to escape.

Mr. Stanley, on taking charge of the case, enlarged the opening into the articulation, and gave exit to a great deal of pus mixed with blood. No change of importance occurred for the next few days, except that the whole texture of the thigh assumed a boggy feel, and fluctuation was detected on its inner side. An exploratory incision was made both on the inner and outer aspect of the thigh. Serum mixed with blood was evacuated, and the probe, passed into the wound, struck upon bone. Mr. Stanley removed the thigh high up by the flap operation, the patient being under the influence of chloroform. There was destruction of the synovial membrane and cartilage, abundant purulent secretion, principally from the denuded bones, and infiltration of pus in the tissues surrounding the joint.

The boy progressed extremely well for the first eleven days, when he fell into an apathetic state, after being very restless. The next day, severe pain in the left side of the chest was complained of, accompanied by rigors. A pericardial friction sound was heard over the apex of the heart, but at no other part of the organ; and a pleuritic rubbing sound was detected, after each inspiration, below the left axilla. On the right side the breathing was coarse and loud, but no morbid sounds were made out. Delirium was the chief sign for the next few days, with some abatement of the pain. A consultation being held with Dr. Roupell, sedatives and stimulating expectorants were ordered; but the patient fell into a state of coma, the wound ceased discharging, and he died on the 4th of November, sixteen days after the operation.

EXAMINATION OF THE BODY. The left pleura was full of thin puriform fluid, which flowed out when the thorax was opened. The lung was covered by a thick layer of rather firm lymph, extending over the whole surface, and also partially between the lobes. The organ itself was considerably compressed, not consolidated, and much heavier than natural. The interior of the lung was full of puriform deposit, consisting in every part of circumscribed masses of soft lymph, which yielded under pressure. Towards the inferior margin, the pulmonary substance was seen through the pleura to be of yellow colour, and on cutting into this part pus flowed out; the tissue itself was soft, easily broken down by the finger, and appearing to have had suppuration. The lung and pleura were removed on the right side, save two circumscribed deposits of lymph.

base of the lower lobe. Puriform fluid issued from the trachea on an incision being made into it. The pericardium and heart were quite healthy.

The stump presented complete want of activity, the ligatures were not detached, and the femoral vein, to the extent of about two inches from its extremity, was plugged with a firm coagulum; above this spot the vein was found filled with pus and blood, as were also the deep femoral and iliac veins, as high as the inferior cava. On the coats of the vessels, which were much discoloured, were deposits of lymph in various places.

CASE IV. William H., aged 18, a labourer at a wholesale corn-dealer's, was admitted into St. Bartholomew's Hospital, April 12th, 1853, under the care of Mr. STANLEY. No scrofulous taint was traceable in the family, and the patient had enjoyed very good health up to a few days before his admission, when he began to feel uneasiness in the left knee. This turned to actual pain, though he had experienced neither blow or fall upon the joint.

On examination, the left knee was found swollen and extremely tender to the touch; the least motion of the joint gave pain, and the febrile symptoms ran high. Mr. Stanley had leeches applied to the affected part, and subsequently emollients; internally the patient had diaphoretics, mercury, etc., and was well supported.

The progress of the inflammation was somewhat checked by the vigorous antiphlogistic measures employed; but formation of pus took place, and the purulent matter burrowed up the thigh. The abscess was opened in several places successively, and fistulous tracts became established, the pain and distress not thereby diminishing. Tonics, opium, good diet, wine, etc., were sedulously had recourse to; but it soon became evident that the local mischief was bringing on hectic fever, and that no means could save the patient's life but amputation. To this measure, however, the patient would not give his assent.

The patient became more and more weak, in consequence of irritation and abundant suppuration; and one week after Mr. Stanley had mentioned the necessity of operation, the boy requested that amputation should be performed. On the 14th of May, 1853, one month and two days after admission, Mr. Stanley removed the limb.

On examination of the joint, it presented thickening of synovial membrane, destruction of the cartilages, and caries of bone. It was thought that the periosteum of the femur had suffered, as a large abscess was discovered in front of the thigh; but the bone and its covering were found healthy. The apertures on the tegumentary surface around the joint were observed to communicate with the latter, and extensive suppuration had evidently taken place in the articular cavity.

The patient did well.

CASE V. A youth, aged 19, was admitted into Bentley ward in St. Bartholomew's Hospital, under Mr. LAWRENCE, May 21st, 1852. He had been suffering from gonorrhoea about one month; the discharge on admission was very slight. He had, however, for some days past been suffering from acute pain in both ankles and in the right knee. On examination, these parts were found very tender to the touch, some swelling existed in the knee-joint, and severe pain was occasioned when passive flexion of the articulations was attempted. Half an ounce of lemon-juice in camphor-mixture was ordered to be taken every sixth hour. Mr. Lawrence also desired leeches to be applied to the affected joints. This medication was continued for several days, but the lemon-juice produced no distinct effect upon the arthritic symptoms; it was therefore left off, and the pure antiphlogistic treatment pursued. The pain and inflammation in the ankles gave way in a short time, but these symptoms became more and more intense in the knee, and suppuration took place, and all the unmistakable signs of hectic fever set in.

Mr. Lawrence amputated the leg, by the circular operation, six weeks after admission. The joint was found much disorganised, and presented acute inflammation of the synovial membrane, suppuration, and loss of cartilages.

The recovery was rather slow, a portion of the femur having become necrosed, but the boy was eventually discharged with a good stump. About a twelvemonth after the operation, the patient was in good general health, with a serviceable stump.

CASE VI. George D., aged 37, a thin, weakly looking man, with fair complexion and red hair, a ladies' shoemaker by trade, was admitted October 8th, 1852, into St. Bartholomew's Hospital, under the care of Mr. STANLEY. At the age of sixteen, the patient slipped on a frosty day, and fell upon his right knee; he was forthwith taken to the London Hospital, and placed under the care of the late Mr. Andrews. He stayed two months in that institution. The acute symptoms were relieved by appropriate treatment, and he was discharged in good con-

dition, being able to use the right limb as well as before the accident.

A few months afterwards, the patient sat for some time on damp grass, and was immediately attacked with severe pain in the knee; the joint swelled very rapidly, and he repaired to the London Hospital. When the more urgent symptoms had been subdued, and the chronic stage had set in, Mr. Andrews proposed amputation, which was accepted by the patient. When the latter had been placed on the operating-table, the late Mr. Scott remarked that the limb might perhaps be saved. The patient was eventually discharged, and placed himself under Mr. Scott's care, who for a twelvemonth applied his strapping to the patient's knee. Partial ankylosis was at last obtained, and the man, for the following twenty years, could use the joint to a limited extent, and with tolerable comfort; he, however, was liable to occasional fits of pain, and seldom walked without a stick.

At Christmas 1851, about twenty-one years after the original accident, the patient caught cold, and was seized with severe pain in the joint. It swelled rapidly, and he was incapacitated from walking. When these symptoms had partially abated, the man repaired to a place where this chronic affection was treated with cold applications and globules. Not having experienced any benefit after six weeks' stay, (as might easily be foreseen), he placed himself under the care of Mr. Stanley. Good diet, tonics, poultices, and subsequently gutta serena splints to the knee, were employed; the general health improved slightly, but it was plain that the carious state of the joint was such that the irritation might shortly destroy the patient. He was, however, discharged two months after admission, but returned soon afterwards with renewed pain in the joint. Mr. Stanley now stated that no course but amputation was left, and the patient returned to Gravesend (his place of abode) to consider the matter.

The patient was subsequently seen in the London Hospital, where he remained but a few weeks; no measures short of amputation being available.

CASE VII. J. W., aged 14, was admitted into St. George's Hospital, under Mr. HAWKINS, Dec. 8th, 1852. The patient had, about a twelvemonth previous to his present admission, been received into the hospital for acute inflammation of the synovial membrane of the right knee-joint. He remained several months under treatment, the inflammation was subdued, and he was discharged with a partially ankylosed knee. He was desired to wear a splint for some time, so that the process of ankylosis might be favoured; but he did not attend to the directions given; the splint was soon cast off, the limb freely used, and new inflammation excited.

He was re-admitted, and it was soon observed that pus had formed in the joint. The abscess was opened some time after admission, to give the patient a chance of ankylosis forming again; but the system now gave way under the irritation of the articular suppuration. Amputation was performed on March 17th, 1853, almost three months after the boy's re-admission.

Mr. Hawkins found a small quantity of pus within the knee-joint; the cartilages both of the articulating surfaces of the femur and tibia were absorbed, a granulating surface appearing in their stead. This boy progressed very well, and the stump was, on May 10th, completely cicatrized.

CASE VIII. W. C., a brick burner, aged 57, was admitted into Charing Cross Hospital, under Mr. AVERY, September 6, 1852. About two years before admission, he slipped and almost fell upon the right knee, in which joint he had for a considerable period had rheumatic pains. The uneasiness following the accident was not severe, for the man bore it about five months. At the expiration of this period, swelling and pain occurred, without any fresh cause. The usual remedies were then resorted to, and temporary improvement was several times obtained; but the external enlargement of the joint, the constant, though not very distressing pain, and the inability to walk with comfort, continued. The right knee-joint was found considerably enlarged; it felt tough, slightly elastic, and neither flexion nor pressure seemed to give the patient very great pain. No external opening was noticed, and no symptoms of suppuration in the joint was present.

Mr. Avery ordered the joint to be painted with the æthereal tincture of iodine,* and prescribed at various times iodide of potas-

* The fluid consists of sulphuric ether, which is made to take up the maximum amount of iodine, the tincture thus becoming very strong. The effect being powerfully derivative, has been found very satisfactory in several instances.

sium, colchicum, liquor potassæ, etc. The local application of iodine procured some improvement.

Severe inflammation recurred after several months, and suppuration took place in the joint; the abscess was opened, and a considerable quantity of pus evacuated.

Several months elapsed, during which the patient had generous diet and stimulants; but the morbid state of the knee-joint at last produced alarming exhaustion, and amputation was performed on 25th April 1853, by Mr. Luke's antero-posterior flap method. The joint, on being opened, presented thickening of the synovial membrane, connected with the suppurative process; but the articular cartilages were not attacked. The patient did well.

CASE IX. R. G., a grocer's shopman, aged 34, of dark hair and complexion, and nervous temperament, was admitted into the London Hospital, under Mr. ADAMS, on the 5th of April, 1853. When sixteen years of age, he had a slight fall upon the right knee, which caused very little pain at the time of the accident; but a few weeks afterwards the joint was attacked with severe inflammation, matter quickly formed, and a considerable amount of pus was evacuated on the abscess being opened. The patient was laid up for a twelvemonth, during which time active suppuration continued. The openings made around the joint healed up. Partial ankylosis probably took place, and for sixteen years the man contrived to attend to his occupations, sometimes requiring the support of one or two sticks. Pain and uneasiness recurred at intervals.

The patient now and then fell, but he generally experienced little pain or trouble from these accidents; but about five months before admission, he fell over a piece of orange-peel, and injured his knee so severely that he was unable to get up. He was now laid up for several months at his own house; matter formed in the joint, the abscesses opened spontaneously, the tibia became dislocated backwards, and the pain was very severe. The patient at last applied at this hospital.

The knee was found considerably enlarged, the outline of the joints lost, the tibia dislocated backwards, and the textures unyielding. Movements of flexion, extension, or rotation, gave very great pain; there were several apertures around the joint discharging pus, and the general health was much impaired.

Mr. Adams endeavoured for four weeks to improve his health by good diet and tonics. Amputation was performed on 7th of May, 1853.

When the joint was cut open, it was found that none of its textures could be recognised; the suppurative process had destroyed the originally thickened synovial membrane, and nothing was discernible but carious bone. At first traumatic fever ran high, and the patient's great debility was very alarming; but he struggled through this stage by the aid of good diet, tonics, and wine.

CASE X. W. S., aged 19, was transferred to Mr. ERICHSEN from the Physician's Ward, in January 15th, 1853, with chronic inflammation and thickening of the synovial membrane of the right knee. The limb was encased at once from the foot to the hip in a firm starch bandage. Very great relief was experienced, the pain and startings seeming much controlled. Small doses of bichloride of mercury in decoction of sarsaparilla were ordered. The apparatus was worn for twelve days, when the patient complained of pain in the joint; to relieve this the starch bandage was removed, twenty-four leeches applied to the knee, and the limb placed on a pillow. A week after this the starch bandage was again put on, as the inflammatory symptoms had subsided. The patient now remained free from pain, and soon began to walk about the ward with his leg in a sling. The apparatus was left on for almost one month, when it was cut up, and the limb ordered to be rubbed with the following liniment, to promote absorption: iodide of potassium, one drachm; soap liniment, one ounce.

A few days afterwards, Scott's strapping plan was adopted for the knee, and in a fortnight's time the patient could bear considerable weight on the limb. Cod liver oil was now substituted for the bichloride of mercury, and on the 29th of March, the patient could walk on the affected leg.

SECONDARY DISEASE OF THE KNEE-JOINT FROM DISEASE AND INJURY OF NEIGHBOURING STRUCTURES.

The *Lancet* for June 18th and 25th contains an account of several cases, in which the knee-joint became affected in consequence of disease or of injury of the structures in its vicinity.

CASE I. J. H., aged 37, a stout, plethoric man, who had much indulged in drinking, was admitted into King's College Hospital, under Mr. HENRY LEE, in September 1852.

Six months before admission, he snapped the patella transversely on the right side. For this injury he went to St. Bartholomew's Hospital, where he remained three months. The fragments were then half an inch apart, and the patient able to walk fairly. A month after this, he slightly hurt the knee again; but he was well in a week.

On September 17th, 1852, three days before admission, the patient was attacked at two o'clock in the morning with a fit of shivering, which lasted until the middle of the day. Since the first accident he had experienced a sense of tightness in the popliteal space; this left him when the shivering came on. As soon as the rigors had ceased, he began to feel pain in the injured knee, which became swollen, red, and tender.

Leeches were applied above the patella, and a blister on either side of the joint. These, however, gave no relief.

Shortly after the patient's admission, the knee being much swollen, and fluctuation easily discernible at the side, an incision was made on either side of the joint, and about three ounces of thin purulent matter escaped from an abscess between the fractured ends of the patella.

On the third day the knee was more swollen and red, and on passing a probe into the wound on the inner side of the joint, some clear fluid exuded. This opening was then extended towards the back of the knee for about two inches, and downwards for about one inch.

On the following day the skin over the joint was of a deep red colour, and the parts around much swollen; there was considerable tension about the wound, and on introducing the finger, the lower part of the inner condyle was distinctly felt, as also the rough exposed surfaces of the patella. Both the incisions were enlarged, and a quantity of purulent matter escaped.

On the fifth day the swelling and redness had much subsided, but the patient remained in a very precarious state for the next eleven days; the wounds discharged profusely, and he had several shivering fits. Mr. Lee had him placed under the influence of chloroform, and made an incision on the inner side of the upper part of the leg, from which much pus escaped.

For the next few days the patient suffered repeated rigors, and Mr. Lee made more incisions in the leg. The man died October 16th, twenty-six days after admission.

EXAMINATION OF THE BODY. The patella was broken transversely, the fragments being about half an inch apart. From the apex of the lower fragment a small piece was detached and necrosed; the cartilages were in several places absorbed on the articular surfaces of the femur and tibia; the crucial ligaments were destroyed, and extensive suppuration between the hamstring muscles, the soleus, and gastrocnemius, had taken place. The femoral vein appeared healthy, and its lining membrane was not discoloured; but at the junction of the profunda vein was some whitish matter, which Mr. Lee judged to be softened fibrin. In the lungs there were small purulent deposits. On making a longitudinal section, the femur was found perfectly healthy.

CASE II. J. G., a cab driver, aged 36, who had not been very temperate, was admitted into the Middlesex Hospital, under Mr. SHAW, April 12th, 1853. He received a short time before admission a kick from a horse, by which the upper part of the left tibia was injured. The wound was not alarming, and matters went on well for a few days; but the soft parts having ulcerated, the bone became exposed, and exfoliation commenced. The wound became unhealthy, and the superficial veins of the leg and thigh showed signs of inflammation. A slight attack of erysipelas also took place. Severe pain was complained of, and it was suspected that suppuration was taking place in the articulation. The fever ran high; the matter came to the surface, and the abscess which had formed in the cavity of the joint was opened. The discharge of pus was profuse, and it became apparent that irritative fever would destroy the patient. Mr. Shaw therefore took off the leg on the 20th of May, 1853. On examination, the joint was found distended by offensive pus; the cartilages and ligaments were softened, the former presenting a flocculent appearance. The abscess of the joint had burrowed under the extensor muscles, and formed an enormous sac.

The patient remained very weak, and in spite of the exhibition of tonics and stimulants, he died nine days after the operation.

CASE III. R. S., aged 48, was admitted into St. George's Hospital, under Mr. H. C. JOHNSON, July 14th, 1852. About six months before admission, he had swelling and pain at the lower part of the femur. An abscess subsequently formed there, and was opened on the inside of the thigh. On admission, the internal part of the latter presented a sinus leading down to the bone; pain was still continuing, and there was a copious discharge of matter. Examination

tonics, good diets, etc., were resorted to; but, after a few weeks, the knee-joint became involved; and the patient's health was giving way under the disease. Amputation was performed Oct. 21st, 1852. Mr. Johnson found the articular cartilages destroyed, the cavity full of pus, the inner side of the joint partially ankylosed, and the patella attacked with caries. Numerous sinuses opening by the inner side of the femur communicated with the articulation. The femur was enlarged and hardened.

After the operation, the patient went on pretty well for a few days, except that the bowels were obstinately constive. On the sixth day, however, the man had rigors, followed by vomiting, profuse diaphoresis, and the well known symptoms of purulent infection. He died on the ninth day after the operation.

CASE IV. W. M., a gamekeeper, aged 30, who had apparently lived freely, came to St. George's Hospital Jan. 5th, 1853, under Mr. HAWKINS. He presented, in the vicinity of the right knee, a fluctuating swelling, which had existed for about nine months, the exciting cause being unknown. The tumour was circumscribed, and situated over the head of the tibia; but the joint was not obviously involved, as the patient complained of no pain, and the synovial cavity did not seem enlarged, though the knee was stiff. It was a question whether the swelling was the result of a collection of purulent fluid, or of the distension of a bursa. An exploratory puncture was made; and, as the liquid which escaped was clear, it was determined to excite absorption by blisters and solution of iodine.

This course was persevered in for about two months, but the swelling did not diminish; it was again punctured, and this time contained pus. The tumour was therefore laid open. The abscess had in the meantime increased in size, the affected limb was much larger than its companion, and the patient's appearance worse than on admission.

The sac was at first thought to be superficial to the joint, and was opened by a small incision almost two months after the first examination; but soon after this the collection of matter increased rapidly; the patient was seized with intense pain in the knee; he had startings in the limb, and slept very badly. He had slight cough, but no disease of the lung was detected. The urine was high coloured, but healthy; the abscess extended to a great depth; and bone could be felt by the probe, apparently close to the head of the tibia.

After about three weeks, as the patient's health was suffering, amputation was performed by Mr. Hewett, in the absence of Mr. Hawkins, on April 14th, 1853. The incision was circular, and made about the lower third of the thigh; it ran through the cavity of the abscess. The anterior portion of the stump was much thickened by serous infiltration, and rendering it impossible to bring the margins of the wound into apposition immediately after the operation. This also prevented the small vessels from retracting, so that almost thirty ligatures were required.

On examination of the joint, its cavity was found to communicate freely with that of the abscess, the cartilages were almost destroyed, and the exposed surfaces of bone carious and partly united by soft ankylosis.

The patient progressed well for sixteen days, but on the seventeenth day he had a severe rigor, followed by an abundant perspiration, and the symptoms of purulent infection became manifest. The face turned very yellow; rigors and perspiration recurred at intervals; the bowels became very weak; the tongue foul; and, after a few days, delirium set in. Still the stump looked healthy; there was plenty of soft parts to cover the bone, and they did not retract. The patient died on May 8th, 1853.

EXAMINATION OF THE BODY. The body was enormously obese, the integuments very yellow. The left leg had been amputated above the knee; the stump was well formed; and the flaps uniting well, but not quite cicatrised. On exposing the divided bone, the muscles around were found very soft and pale; dark looking purulent fluid enclosed about three-fourths of the circumference of the femur, the periosteum being destroyed to a corresponding extent; the bone itself, as well as the medulla, were healthy. The superficial veins of the thigh were natural, but the femoral and tributary branches were full of discoloured red and brown pus-like fluid, and of coagulated fibrin, adherent and non-adherent to the coats of the vessels. Some of the smaller veins, near the lower part of the thigh, contained pure, light coloured, yellow pus. The lower part of the vena cava inferior, as high as within two inches of the diaphragm, as also the left common iliac, the left internal and external iliac veins, all contained similar material to that within the left femoral vein. The right common iliac and its subdivisions were natural. Nothing remarkable was noticed in the abdominal viscera; the pleural cavities were healthy, but the

lungs were congested; and in the lower part of one of them was a small yellow deposit of fibrin, surrounded by firmer structure than the rest, and beginning very slightly to soften. There was secondary lobular pneumonia; and the blood was generally very fluid.

CASE V. Amelia M., aged 15, was admitted into University College Hospital, under Mr. ERICHSEN, November 26, 1852, with pain and swelling of the lower part of the left thigh, which she attributed to cold taken about three weeks before. The girl presented the signs of a strumous diathesis. Mr. Erichsen, on examining the part, convinced himself that very rapid formation of matter had taken place; an incision was made three inches above the patella, whereupon about ten ounces of very foetid, oily pus escaped. A probe could be carried for four or five inches along the denuded bone. Poulices were placed around the affected parts, and stimulants and diaphoretics were given. Three days after this, a large quantity of foetid pus was evacuated by another incision, the same treatment being continued. Soon after the opening of these abscesses, the patient began to show symptoms of exhaustion, and Mr. Erichsen proposed amputation. The friends of the girl objected to the operation. Under these circumstances, efforts were directed to counteract, by tonics and stimulants, the debilitating effects of suppuration. Good diet, wine, quinine, the mineral acids, etc., were therefore ordered.

For five days the wound poured out up to ten ounces of pus *per diem*, and the patient became accordingly very much emaciated, and hectic set in. The appetite remained, however, good, and the perspirations at night began to diminish. On the twenty-eighth day, the discharge was about ten ounces a day, the feverishness continued, the pulse was 130, the skin hot and dry, and the appetite falling off. The patient began also to complain of the knee on the affected side. The joint was found to present an abnormal fullness. The knee became gradually flexed, and the discharge from the abscesses around the thigh began to diminish. The contraction increased; and in about fourteen days from the time when the swelling of the knee was first noticed, the leg had been drawn up at a right angle with the thigh. The knee now presented a considerable uniform enlargement, the integuments were red and shining, and fluctuation was quite distinct. The probe could still be passed very high along the sinuses of the thigh; but the girl's spirits were better, her appetite became ravenous, and the bowels remained very regular.

On the 1st of February, the abscess in the cavity of the joint broke spontaneously, and the pain and swelling almost disappeared. The discharge from the thigh and knee gradually lessened in quantity, and the wound in the joint healed in one month. The patient's general health improved, the purulent matter coming from the thigh became very trifling, and the knee was getting ankylosed in a state of extreme flexion. At the fourth month of her stay in the hospital, the girl was put under the influence of chloroform, and the limb was forcibly extended; it was then placed on a splint, and given a few days' rest. The patient was finally discharged in a fair way to complete recovery, with a very small sinus in the thigh.

CONTRACTION OF THE KNEE-JOINT: DIVISION OF THE HAMSTRING TENDONS.

The *Medical Times and Gazette*, for February 10th, contains the following cases.

CASE I. W. C., aged 14, a tolerably healthy looking boy, was admitted into the Royal Orthopædic Hospital, under the care of Mr. LONSDALE, on July 7th, 1852. His right knee was contracted at an acute angle. The foot was everted, and the tibia partially dislocated backwards and outwards. By forcible extension some movement could be accomplished. The lad stated, that the disease had resulted from a "white swelling" in the first year of infancy, which had been attended by long continued inflammation, but never produced an abscess. He had ever since walked with crutches, and was but just able to touch the ground with the toes of the right foot. All inflammatory symptoms had disappeared some years ago, and he had himself also much improved in health. The hamstring tendons were tense. On July 8th, subcutaneous division of the tendons of the semitendinosus and biceps muscles was performed. The puncture in the skin was in each case small; and the limb having been bandaged to a splint which had been previously moulded to its bent position, the wounds were, in the course of a few days, quite healed. On July 15th, a week after the operation, the apparatus for effecting extension was adjusted, and without pain the knee was considerably extended. Once in every two or three days, the extending

force was increased by turning the rack-screw at the knee, the infliction of pain being carefully avoided.

On Sept. 20th, the limb was almost straight. The tibia of the diseased side was nearly an inch shorter than that of the other. An apparatus was prepared, consisting of a high soled boot, to each side of which was attached a flat steel bar, extending to the middle of the thigh, and having, on each side of the knee-joint, a hinge permitting flexion and extension at the will of the surgeon.

On Oct. 6th, he was allowed to return home, being able to walk about, with the apparatus above described, with great ease.

CASE II. M. A. M., a fair complexioned girl, aged 7, when two years old, had suffered an acute inflammation of the left knee-joint, which terminated in abscesses. These broke externally, and continued to discharge up to the present time. For a considerable period her life appeared in danger, but she ultimately rallied, and the acute inflammation subsided, leaving her knee contracted. When admitted into the Orthopaedic Hospital, under Mr. TAMPLIN, on June 8th, 1852, there was very little swelling and no pain; a sinus on the outer side of the joint continued to discharge a small quantity of thin pus. The knee was contracted at a right angle, and had but a very slight extent of motion. The tibia was considerably behind the femur; the foot and leg were everted. Mr. Tamplin determined to at once perform subcutaneous division of the hamstring tendons. Precisely the same steps were gone through as in the foregoing case. The operation was performed on June 8th, and in December the knee was all but straight. She had in the meantime much improved in health under the exhibition of cod liver oil; and the sinus formerly existing had quite healed. The head of the tibia remaining displaced outwards, Mr. Tamplin had a broad strap of webbing passed round it, and fixed to the inner bar of the apparatus. By this means constant pressure is kept against the bone, tending to draw it inwards. On February 10th, the position of the bones might be said to be natural, and the patient walked about with great ease, though with a limping gait, on account of there being scarcely any motion in the joint. Throughout the treatment she suffered scarcely any pain.

CASE III. M. S., aged 32, fair complexioned and delicate looking, and bearing the remains of strumous affections of the eyes and ears, was admitted into the Orthopaedic Hospital on the 4th of August. Her right knee was contracted at an acute angle, the hamstring tendons being very tense. The tibia was displaced backwards and outwards. There was slight power of motion in the joint, around which were the scars of several sinuses. She stated, that when six years old she had fallen and bruised her knee, which afterwards became swollen and painful. Abscesses formed, and her general health suffered so severely, that several of the surgeons who were consulted advised the removal of the limb. The abscesses continued to discharge for seven years, after which they gradually closed, and all pain ceased. She had never since been able to walk about without crutches, being but just able to reach the ground with the tip of the great toe of the right foot. There was now no existing inflammation of the joint, all swelling and pain having long ago subsided. A few days after her admission, Mr. LONSDALE divided the hamstring tendons, and in a week, the extending process was commenced. She at different times suffered more from pain than is usual during this treatment.

ANGULAR ANCHYLOSIS OF THE KNEE-JOINT TREATED BY FORCIBLE EXTENSION.

The following case is reported in the *Lancet* for Jan. 29th.

CASE I. Harriet H—, aged 26, a waistcoat maker, of dark complexion and nervous temperament, was admitted into Charing Cross Hospital, Dec. 13th, 1852, under the care of Mr. HANCOCK. The father and mother were alive, and no scrofulous manifestations had been noticed in her brothers and sisters. Six years ago, without any violence, the knee began to swell and become painful after exposure to wet. For three years she did not resort to remedial means, though much inconvenienced by swelling and pain. The patient then went to a surgeon, who leached and blistered the joint; this did not relieve her, and incomplete anchylosis became established; some motion remained in the limb, being, however, accompanied with much pain. Six months after this, another surgeon cupped the joint; and, lastly, as the knee was forcibly and permanently flexed, the patient was made to wear steel rods and circular fastenings, with a screw at the back, so as to promote gradual extension of the limb. She would have improved under this treatment, had she worn the apparatus long enough; but it gave her so much pain that after seven months she left it off, and the joint was as contracted as ever.

Mr. Hancock considered that the articulation might be forcibly extended under the influence of chloroform. The knee was very much swollen, and there was a great deal of pain in the joint. On the 10th January the limb was forcibly extended whilst the patient was insensible with chloroform, and it was immediately placed upon a splint and firmly secured to it by a roller. There was much pain in the joint for the first four days; this, however, decreased gradually, as well as the size of the swelling. The limb became straight, the patella lying very high over the condyles, and the knee remained painful. The general health was good.

Mr. Avery also treated cases of this kind with great success; in one of them, a boy about ten years old, the pain persisted, however, a long time.

The next case is related in the *Lancet* for June 11th.

CASE II. A woman, aged 20, was treated in St. Bartholomew's Hospital, in 1842, by Mr. STANLEY, for acute inflammation of the synovial membrane of the knee-joint, which gradually subsided under appropriate means, and passed into the chronic form. Setons, moxas, etc., were used, and when the woman's health began to fail, she was advised to submit to amputation. She objected, however, to the operation; and was eventually discharged with a contracted knee.

This patient returned to the hospital eight years afterwards to have the limb straightened. This was done forcibly whilst she was under the influence of chloroform, and she again left the hospital after a few weeks' stay, with an angular splint and screw.

In July 1852, the woman had worn the apparatus for some time; the leg was straight, and there was slight motion in the knee-joint. Mr. Stanley advised her to use support at the back of the leg, and to be careful of herself, the more so as she had occasional pain in the articulation.

DISEASES OF CHILDREN.

INFLAMMATION OF THE LYMPHATIC GLANDS IN A CHILD, FOLLOWING VAGINAL CATARRH.

In the *Deutsche Klinik* for April 16, Dr. F. GUENSEBURG relates the following case.

On March 10th, he was called to see a child aged 5 months, who, after having had a mucous discharge for three days from the vagina, had hardness, swelling, and redness of the labia. An intense general redness extended also to the inner part of the thighs. There was no discharge from the mucous membrane, which was thickened, and of a dark red colour. The pulse was 140; the respirations were 48; the tongue was dry. The child took the breast, and appeared cheerful; the brain was unaffected; it had two stools daily.

In the following days, the redness of the integument, with much swelling of the subcutaneous tissue, extended as far as the knees, and as far as the middle line of the abdomen; and the back part of the body and the extremities became of a dark red colour. On the anterior part, as far down as the knees, and as high as the umbilicus, there was a red network, of which the cords were in some parts visible, and in others could be felt.

On March 13th, the swelling and redness of the genital organs had diminished; but the knees and feet were much swollen. The redness was general, and limited to the level of the umbilicus; the fever was diminished; the child slept tolerably quietly, and took the breast, but constantly moaned. The inguinal glands were felt as little globular masses.

On March 15th, there were severe rigors for two hours; after which the redness extended over the whole of the back as high as the neck. Broad serpentine lines extended also on each side, from the axilla to the middle line of the sternum; and the axillary glands were swollen. Tartrate of potash and calomel were given; but the progress of the disease was not thereby interrupted.

On March 16th, the swelling of the feet diminished.

On March 17th, there was another violent rigor; after which the redness extended over the shoulders as far as the insertion of the deltoid muscles, and up the neck over the whole of the head. Bunches of red lines extended outwards behind the ears, and forwards on the neck. The submaxillary glands were swollen. Since the 15th, chlorinated water had been used.

On March 18th, a repetition of the rigor was followed by swelling and redness of the upper arm and chest. The redness extended also as far as the hand.

After March 19th, the rigors did not recur. The skin gradually became brown; while the swellings of the feet

axilla, groins, and maxillary regions, were removed, the streaks of congestion on the skin gradually changed colour, and totally disappeared on March 27th. Two lymphatic glands on the feet remained hard longer than in other parts.

REMARKS. The anatomical position of the lines of redness and swelling, as well as the sequence of the symptoms, shewed that the ingestion of the cutaneous capillaries, as well as the exudation into the subcutaneous tissue, were results of inflammation of the lymphatic glands. The rigors constantly preceded the extension of the exudation from one region to another. Whether there was also a local transplantation of putrid matter, cannot be ascertained.

Dr. Günsburg was unable to determine the causes of the affection, on the supposition that putrid matter had been transmitted through the lymphatic vessels of the patient. There was nothing in the hygienic condition of the child to account for it. The parents lived in a healthy dwelling, and were of clean habits.

ASSOCIATION INTELLIGENCE.

MIDLAND BRANCH: NOTICE OF QUARTERLY MEETING.

The Quarterly Meeting of this Branch will be held at the Town Hall, Leicester, on Thursday, September 1st, at 2 o'clock.

JOHN BARCLAY, M.D., *Hon. Secretary.*

SUFFOLK BRANCH: FIRST SOIRÉE MÉDICALE.

Members of the Suffolk Branch are requested to observe that the first of a proposed series of Soirées Médicales will be held at the White Horse Hotel, Ipswich, on Friday, the 2nd of Sept., at 7 o'clock P.M.

JOHN KIRKMAN, M.D., *Hon. Secretary.*

EDITOR'S LETTER BOX.

CHLOROFORM IN MIDWIFERY. REPLY TO DR. SIMPSON.

LETTER FROM J. C. BLOXAM, ESQ.

SIR,—Some advance may be made towards settling the question as to the use of anæsthetics in labour, by exposing the errors in reasoning of the authorities who have discussed this subject. Dr. Simpson has endeavoured to shew the errors of Dr. Meigs; and it may be well now to point out the fallacies in Dr. Simpson's arguments.

Dr. Simpson, in his letter to Dr. Meigs, published in the *ASSOCIATION MEDICAL JOURNAL* for July 8th, makes liberal use of a very common, but, at the same time, very fallacious mode of argument; which consists in substituting some other proposition for the one primarily under consideration. The adopted proposition is made good, or it is perhaps admitted to be so, or it is at any rate assumed to be so. No attempt is made to shew that the two propositions are similar, analogous, or parallel to one another; but as there is an obvious or apparent resemblance in some point of view, they are assumed to be parallel cases for the purpose of the argument. This is a very hazardous mode of proceeding, though a very convenient one in some respects. The analogy ought to be closely examined before it is trusted to.

The two cases advanced as analogous ones, in the fourth paragraph, are glaringly unlike, as regards the point in which they ought to be alike. Certainly the sensations, or the expressions, of the patient would afford a very bad indication as to what structure was being injured during a surgical operation; and far more trustworthy indications would be at the operator's command; but this does not shew that the parturient patient's sensations would not give more trustworthy evidence than any anatomical knowledge on the part of the operator, as to whether her structures were or were not being injured by him. In the one case the operator, no doubt, ought to trust his own eyes; but in the other it is evident he ought not; and if he is not allowed to use his eyes, it may be very right to get what assistance he can from his ears. Dr. Meigs proposes to substitute ears for eyes; not ears for anatomical knowledge.

The two propositions that are placed in the same category, in paragraph 14, p. 584, beginning with the words "In your practice", are so placed, with less violence to sound reasoning than occurs in other places: but if these two propositions are to be placed in the same category, as parallel cases, the following proposition may also be ranged with them, viz., if a man be suffering pangs consequent upon the commission of crime, it would be our duty to relieve his suffering, by rendering him drunk with alcohol, or by putting him to sleep with opium. The question of counteracting a depraved action—of relieving the pain of disease—is quite different from that of depriving a human being of reason and consciousness whilst subjected to the natural sufferings, as well as the dangers of a natural process. It is clearly quite *wrong* to render a person insensible to the natural pangs of a wounded conscience. The propriety is, at least, *doubtful*, of rendering a person insensible of the natural pains of childbirth. It is clearly quite *right* to relieve the sufferings of disease. In the last case, we have full authority for the proposition stated. In the second case, we have no authority against the proposition, but rather for its support. In the first case, if there be no authority directly bearing on the proposition, there is much to support it indirectly.

The proposition of Dr. Meigs, which is argued in paragraph 21, p. 184, beginning with the words "But waiving", is not that no means should be employed to moderate the pains of labour, but that women should not be deprived of their reason and consciousness whilst enduring these pains. The act, here objected to, bears no analogy to that of increasing the power of the eye, or of any other organ, in the performance of its natural function by any mechanical contrivance. Neither does it bear any analogy to that of using the means which nature offers plainly to every one for the purpose of protecting the body from mischief. To preclude evil is very different from rendering a human being insensible of its existence. Would Dr. Simpson recommend the use of anæsthesia as a remedy against cold? If not, does not this prove the want of analogy in the cases he brings forward. Or would he, consistently with his doctrine, abrogate life whenever it became a source of discomfort?

The proposition advanced in paragraph 23, p. 585, beginning with the words "The argument", affords a strong example of that want of analogy which is supposed to exist, and yet, so far as any analogy does prevail, it rather serves to discountenance the proposed use of anæsthetics. It certainly is unwise to renounce the ordinary amount of fatigue that attends upon ordinary progression and natural walking. That such fatigue is conducive to the health and well-being of animals there can be no doubt; and, so far as carriages are used, through the lazy and cowardly desire of avoiding such inconvenience, they are highly detrimental. But the legitimate and ordinary purpose for which horses, carriages, and railways are used, is that of effecting what *can* not be effected by the natural means of progression.

There is, with everybody, a limit to what can be effected by the ordinary use of legs; and when something is required beyond this limit, railways and other means are had recourse to. In parturition there is, on the other hand, a very limited object to be effected, and the natural means, in ordinary labour, are quite adequate to accomplish the object. If it were proposed to enable women to produce a dozen, or a score of children at one birth, by the employment of anæsthesia, the two cases would then be sufficiently analogous to one another, and the same principles would, perhaps, justify both. It is difficult to imagine upon what grounds it can be said that "the practice of wearing a covering for the head was doubtlessly stoutly resisted at first"; probability seems to be quite opposed to such a notion.

No doubt many wise projects and innovations have been objected to for very foolish reasons, and the historian Acosta may have been guilty of such an error; but this does not, by any means, prove every new project to be a wise one. The new project, alluded to in paragraph 25, beginning with the words "Some day", was intended to effect objects which were attainable, or which were supposed to be attainable, by no other means: it was not proposed for the mere purpose of escaping the bodily discomfort which attended upon the means then in use. Moreover, it has not yet been ascertained that this project is a wise one.

In paragraph 26, p. 585, beginning with the words "The truth", the use of forks is alluded to as a means of assisting our hands in lifting portions of meat, etc.; and this innovation is then likened to the employment of anæsthetics in *aiding* the function of human parturition. But there is no objection made apparently to the use of anæsthetics for the purpose of *aiding* parturition, and consequently the two cases are not analogous.

The argument contained in paragraph 29, beginning with the

word "Few", has, in fact, already been answered. However, if a person, having to travel from Philadelphia to New York, should inquire of his medical adviser whether he should make the journey on foot, the doctor would, very probably and very properly, give his professional opinion that it should be made on foot. But the querist would, very probably and very properly, adopt the railway: he would determine to disregard the benefit he might gain to his health by walking, considering that the saving that the railway would effect, in point of time, would be a full equivalent for what he might lose in other respects: and this he would do, consistently with admitting the soundness of the medical opinion.

The analogy between the two cases, in paragraph 31, p. 586, beginning with the words "But let", is by no means strong. Would Dr. Simpson, if he were travelling on a railway, and found that some accident had happened to the engine, which made it likely to explode, or to overturn the train, or to render a continuance of progression in any way painful, wish to be subjected to the influence of chloroform? It is to be presumed that he would not; and yet this case is surely more analogous to that of the parturient woman than the one which he advances. The parties, in each case, would wish to prevent the pain and danger, but they might very reasonably object to deprived of consciousness during their continuance. In the case suggested by Dr. Simpson, the party concerned would prevent the evil by not incurring it. The case of the parturient woman would be far more analogous to the case suggested, if the question at issue were, whether the woman should subject herself to the pains of parturition, instead of whether she should be deprived of consciousness during their continuance.

The two cases advanced in paragraph 33, p. 586, beginning with the words "And indeed in a new practice", are not analogous. In the case of the parturient woman, that she incurs additional danger to her life, in order to escape merely temporary pain. In the case of the traveller (taking the case precisely as it is given), there is no additional danger incurred. Railway travelling appears to be the safest travelling; and the railway advocate need not reproach himself, if the safer plan of the two, which he advocated, happened to terminate in mischief. Even if the two plans were, apparently, equally safe, or if the advocated plan merely substituted one danger for another, the argument would stand the same; but it is quite different when danger is substituted for pain. If a person were consulted and trusted, in a professional capacity, as to which of two modes of locomotion should be adopted, and he selected the dangerous mode as opposed to the painful—the duration of the pain being coterminous with that of the act occasioning it—and the selected dangerous mode should prove fatal, the adviser would then perhaps very properly reproach himself for the advice he had given; he would perhaps for the future advise his client, or his patient, to adopt the safe mode; or, if the pain of this could not be borne, that the journey should not be undertaken at all. That is to say, he would advise that the inconvenience should be endured with courage and resignation, or else, that the alternative between pain and danger should not be incurred. As to the traveller being destroyed by making the journey on foot, there is no moving in any way without danger from unforeseen occurrences; but her being destroyed by the fatigue of the journey would depend, not upon the length of the journey, but upon the expedition with which it was effected, and other circumstances.

The analogy suggested in paragraph 35, p. 587, beginning with the words "But I proceed", is, to some extent, a repetition of what had been advanced before; but, as it is connected with other supposed analogies, in several following paragraphs, some observations may be made upon them together, and these may not perhaps always be limited to the question of analogy. Dr. Simpson appears to use the expression, "the general condition of man", in a different sense from that in which Dr. Meigs uses it; and it becomes desirable to consider what ought to be included in the expression, as well as what each party does include in it. Dr. Simpson appears to give a much larger scope to the meaning of the expression than Dr. Meigs does. There is a natural, normal condition of man; and there is an abnormal, perverted condition of man. There is a condition of man which is brought about by disease, accident, folly, or vice; but this surely is not the condition that ought to be understood as Dr. Meigs's "general condition of man". Disease is, no doubt, very general, and death is incurred by all; but, nevertheless, it is not the general condition of man to be suffering from any individual disease, nor to be dying at any particular time, or in consequence of any particular disease; and we may, very properly and consistently, cure any particular disease, which is

a perverted condition of man; or prevent death, at any particular time, which is no more a part of the condition of man than life is; and yet feel that we are not attempting to abrogate the "general condition of man". Dr. Simpson appears to confound disease, as the general condition of man, with a disease, as the particular disease of a man. There is no doubt that it is quite legitimate to abrogate any abnormal condition, however common it may be, of man; but it does not follow from this, that it must in all cases be legitimate to attempt the abrogation of the normal condition of man. Speaking in a wide sense, man is quite justified in relieving his own or his neighbours' sufferings, and improving their comfort; but much depends, nevertheless, upon the extent to which, and the circumstances under which, this is done. The desire to relieve existing discomfort is, under many circumstances, neither more nor less than temptation to wickedness. If the immediate relief of existing bodily suffering were, in all cases, justifiable, drunkenness, lasciviousness, perhaps all the vices that flesh is heir to, would stand justified. Without attempting to define all that is included in the normal, natural, general condition of man, it may safely be affirmed that the pains of parturition and the toils of labour are within its range; and, if any effort to improve our condition is universally justifiable, that of relieving the sufferings of disease must be so. Dr. Simpson applies Dr. Meigs's doctrines to different circumstances from what Dr. Meigs himself does, and so makes them appear erroneous or ridiculous; but Dr. Simpson's doctrines might be applied to different circumstances, equally analogous with those in the other case, and thus be made to justify acts which he himself would be far from approving. One of the general conditions of man is that of exercising his mind to provide himself with appliances whereby he may enhance the powers of his body; and this extension of the powers of man may continue indefinitely, without offence to the doctrines of Dr. Meigs. The use of railway cars, steamboats, coaches, etc., etc., enables more to be effected with less proportionate danger to life, though with an increase, in many cases, of bodily suffering; and these aids to human industry would not be opposed by Dr. Meigs's doctrines, even if they were attended with an increased mortality; because the benefits to be gained by their use may fully compensate for the increased mortality. But, according to Dr. Meigs, there is no adequate compensation for any increased mortality in parturition through the use of anaesthetics.

Dr. Meigs's theory does not go to show that the practice of medicine should be abandoned. It may fairly be contended that the search for the philosopher's stone, which was to abrogate disease itself, should be abandoned, in accordance with the theory; but not that the existing treatment of individual diseases should be so. The philosophers of a former age, however, might have argued for their proposed innovation in Dr. Simpson's language; pointing out how many innovations had been objected to which eventually proved to be useful. The fact, again, that medicines sometimes do fatal mischief, is not to the point. Dr. Simpson will not deny that, on the whole, human life is economised by the practice of medicine, and that this is its aim and object, whilst the same cannot be said of the employment of anaesthesia. In regard to the use of opium, it must be a very uncommon thing for it to occasion death, except when it is either given for that express purpose, or it is given to children in the same way as anaesthetics are to adults, viz., to abolish their sense of suffering, or else when it is given by some accident or blunder. All the fatal cases quoted by Dr. Simpson most probably come under one or other of these heads.

It seems pretty evident that the use of those things which are absolutely necessary for the preservation of life, and which are referred to in paragraph 37, p. 587, have no analogy to the use of anaesthetics.

The arguments that are advanced by Dr. Simpson in reference to the fifth text are of a different nature from those referring to the preceding texts. If it be the fact, that parturition is rendered more safe by the exhibition of anaesthetics, this constitutes a sound and legitimate, but perhaps not conclusive reason, for their use; but the evidence advanced to establish the fact is very weak. It is very manifest that the same thing may be, and frequently is, salutary and conservative within certain limits, but destructive, nevertheless, when carried beyond certain limits; and this may very well be the case with the pains of labour. It by no means follows that, because short and easy labours prove less destructive than protracted ones, therefore the use of anaesthetics must lessen the danger. It does not at all follow that, because patients, when subjected to the pain and shock of surgical operations without the use of anaesthetics, recover in smaller proportion than those who use anaesthetics, therefore

under their influence, that, therefore, women undergoing the physiological pain of parturition should obtain a corresponding benefit from the same means. It does not follow that this must be the result, by any means; and there is no evidence advanced that the result is so. Neither does it at all follow that, because the parturient female amongst red Indians, and other uncivilised tribes, experiences little pain and little danger, that, therefore, anaesthesia should annul danger in civilised society: the immunity of the savage is not connected with *unconsciousness* of her pain. It will not be disputed by any one, probably, that pain, speaking generally, is deleterious and injurious; but ordinary pain is the result, itself, of some deleterious action; and this certainly cannot be said of the natural pain of labour. May we not fairly presume, then, that the morbid pain and the physiological pain differ as much in their consequences as in their antecedents? Probably neither of the authorities quoted would admit that their remarks are applicable to the pain of labour.

I am, etc.,
JOHN C. BLOXAM.

Newport, Isle of Wight, August 1853.

NEWS AND TOPICS OF THE DAY.

SIR JAMES L. BARDSLEY, M.D.

At a meeting of the Committee of the Manchester Medico-Ethical Association, held on Thursday, Aug. 17th, 1853, it was moved by R. Allen, Esq., seconded by T. Mellor, Esq., and unanimously resolved—"That the following congratulatory address be presented to Sir James L. Bardsley, M.D., President of the Association."

Manchester, Aug. 18th, 1853.

SIR,—Her Majesty having been graciously pleased to confer upon you the honour of knighthood, the Members of the Medico-Ethical Association of this city beg to offer you, the President of this Society, their most cordial congratulations on this distinguished recognition of your high professional character and your individual worth.

While the Association regards this well merited honour as one done to the entire profession, they cannot fail to applaud the selection of yourself, as the person through whom the tribute has been paid—a selection that recognises your eminence as a physician in the largest provincial city in England, and the inheritor of a name that will long be remembered in the profession with respect and admiration.

That you may long live to enjoy the honour which Her Majesty has so appropriately conferred upon you, and thus be a living testimony to your junior professional brethren, of the practical advantages that attend the possession of intellectual superiority and moral excellence, is the earnest wish of the Members of the Manchester Medico-Ethical Association.

(Signed on behalf of the Association.)

W. J. WILSON, } *Vice Presidents.*
J. ROBERTSON, }
D. NOBLE, *Treasurer.*
J. AIKENHEAD, M.D. } *Hon. Secs.*
W. C. WILLIAMSON. }

To Sir JAMES L. BARDSLEY, M.D. etc., etc.

VACCINATION: SUPPLY OF LYMPH. It is perhaps not sufficiently known that fresh vaccine lymph can be at any time procured by application to Dr. Hue, the Registrar of the National Vaccine Establishment, through the Secretary of State for the Home Department. We subjoin a copy of the circular which is forwarded with each supply of lymph.

"National Vaccine Establishment, No. 8, Russell Place, Fitzroy Square, London. Medical practitioners, in all parts of the empire, may be supplied with vaccine lymph, without any expense, from the National Vaccine Establishment.

"You are particularly requested, as soon as you can, after the receipt and use of this lymph, and whenever you repeat, at any time, your application for lymph, to report to the establishment the number you have vaccinated from each supply, and with what result. Pray have the kindness to attend to the above request. (Signed) C. H.

"Surgeons are advised to employ recent *liquid vaccine lymph*, whenever it is in their power; and with this view, to vaccinate their patients in succession, for the purpose of keeping up a supply.

"Letters of application for lymph, and communications respecting vaccination, are to be addressed, *unsealed*, to 'Dr. Hue, Registrar of the N. V. E., Russell Place, Fitzroy Square.' And inclosed in an outside cover, directed thus: 'To the Right Hon. the Secretary of State, Home Department, Whitehall. National Vaccine Establishment.'

"As inoculation of the small-pox is altogether unjustifiable, the Board have resolved, that if any vaccinator of this establishment shall so inoculate, his name be erased from the list.

"It is proper that it should be known, that persons exposing patients affected with the small-pox, and medical practitioners and others who inoculate that disease and concur in such exposure, are liable to a criminal prosecution for the offence."

OZONE: DR. SCHONBEIN'S OZONOMETER. The following circular has been issued by Dr. Drew, of Southampton, who will be happy to receive communications from members of the Association on the subject.

"Winsor House, Southampton, July 28th, 1853.

"SIR,—At a late interview with Dr. Schonbein, at Bâle, I engaged to bring before the notice of meteorological observers in this country, his simple method of ascertaining the amount of *ozone* in the atmosphere. Dr. Schonbein's ozonometer is in general use throughout Germany; and he is anxious that corresponding observations should be taken in England. I beg to inquire whether, to promote this object, you are willing to undertake daily observations for a year, forwarding the results to me every three months, for transmission to Bâle. The expense of ozonometer and register would be about five shillings: the results would be highly interesting, as supplying the means of ascertaining approximately the electric state of the atmosphere. I subjoin a description of the ozonometer, and will thank you to let me know your decision without delay, in order that I may order the proper number, and that observations may be forthwith commenced.

"I have the honour to be, sir, yours faithfully,

"JOHN DREW, F.R.A.S., Ph.D. Univer. Bâle,

"Memb. Council Brit. Meteorol. Soc."

The following is a description of Dr. Schonbein's ozonometer:—

The ozonometer consists of twelve bundles of paper, prepared with iodine and starch: each bundle contains sixty strips, and serves for one month's observations: a spare set is added for additional observations during thunder storms, or whenever the air may appear to be overcharged with electricity. At nine o'clock every morning, a strip of the prepared paper is to be suspended in a spot to which the air has free access, but not the sun. It must be removed from dung heaps, stables, etc., where gases are developed, which would vitiate the observation. At nine o'clock in the evening the exposed strip is dipped in water. It will be found to assume a purple tint. The depth of this tint is compared with the corresponding colour on a scale, on which there are ten gradations, and the number is to be inserted in the register with which it agrees in depth. Another slip of paper must be exposed at 9 p.m., and examined and registered in like manner at 9 a.m., on the following morning. At the close of each month, the mean is to be deduced, by dividing the sum of the numbers registered by the number of observations.

GENERAL BOARD OF HEALTH. On Saturday, a return, obtained by Mr. A. Pellatt, M.P., was printed, showing the operations of the Central Board of Health. Since the formation of the board, in 1848, the amounts received to the end of last year were £55,161:10:8, out of which sums amounting to £51,492:17 have been paid, leaving a balance of £3,668:13:8. The amount repayable by local boards is stated at £10,575. The amounts voted for the annual expenditure during the operations of the act were £53,879:15, exclusive of nearly £3,000, a further sum to be received, and the total expenditure was £51,492:17, as already stated, out of which £40,031:9:5 was expended under the Public Health Act, and £11,461:7:7 under the Nuisances Removal Act. The total amount voted last year was £10,745, and three-fourths were included in the amount stated. The liabilities for expenses incurred to the end of last year were £1,250. The excess in the amount voted over the amount expended for the whole period is £1,130:18. The average annual expenditure under the Public Health Act, after deducting the amount repayable, is stated to be £4,813. The remainder of the return has reference to the documentary business of the board.

APOTHECARIES' HALL:—PASS LIST. Thursday, June 30th, 1858:—St. John Edwards, London; Kennedy Gill, Acerington; Richard Clee Heighway, Shrewsbury; Thomas Hillier, Stroud, Gloucestershire; George Yeates Hunter, jun., Marn Gate; William Naylor Kempster, Whitechurch, Salop; Michael Fenton Manifold, Dublin.

Thursday, July 7th:—John Bolton Adams; John Evans Howard, Llangollen; Joseph Beauchamp Matthews, Oxfordshire; Henry Cooper Rose, Canterbury; Peter Leigh Saddler, Warrington; James Syme, Cumberland; John Henry Thomas, Llanamlet.

Thursday, July 14th:—Cecil Calvert Cogan, Royal Mail Steam Packet Service; Major Greenwood, Wakefield Street, St. Pancras; Griffith Griffith, Saltrenddyn, Merionethshire.

Thursday, July 21st:—Reginald Bayley Walters, Winchester; Alderman Thomas Houghton, Waters; George Skrimshire.

Thursday, July 28th:—William Henry Barber, Longtown; William Fisher Favell, Sheffield; William Smallpage, Knottingley; Joseph Stephens, Probus, Cornwall; Henry Tournay Stiles, Pinchbeck, Spalding.

Thursday, August 4th:—Henry Adge, Bradford, Wilts; John Mathew Butler, Woolwich, Kent; Ephraim Matthews Cridge, Stoke, Devonport; Richard Staines Davey, Walmer; Richard Nowell Halliwell, Dewsbury; Thomas Henslip, Hutton Garden; Thomas Edmund Jacobson, Sleaford, Lincolnshire; John Withington Roe, Malpas, Cheshire; William Salt, Betley, Staffordshire; Richard Sykes, Drightington, Yorkshire; Frederick Savignac Stedman, India; John Tudor, Bronhanloy, Denbighshire.

Thursday, August 11th:—Robert Austen Allen, co. Tyrone, Ireland; John Fox, Weymouth, Dorset; Alfred William Stocks, Salford.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

GOODEVE, E., M.D., appointed Professor of Materia Medica in the Bengal Medical College, Calcutta.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

BANKIER, Dr., R.N., late of H.M.S. *Minden*, at Hongkong, lately.

BROWLEY, C., M.D., at Cleveland Place, Dawlish, Devon, on August 3.

COOPER, Bransby Blake, Esq., Senior Surgeon to Guy's Hospital, suddenly, on August 18, aged 60. Mr. Cooper had for some time been labouring under illness, but had partially

recovered. He was crossing the hall at the Athenaeum Club, when he stopped, and called for a glass of water; before this could be brought, blood spouted from his mouth; he fell, and was almost instantly a corpse.

DEAKINS, Robert Thomas, M.D., Staff Assistant Surgeon 67th Regiment, at St. John's, Antigua, of yellow fever, aged 27, on June 8.

OWEN, William Charles, M.D., at Midnapore, Bengal, of Cholera, aged 27, on May 24.

JUSSEAU, M. Adrien de, Member and President of the Academy of Sciences in Paris, lately.

PHILL, Richard Spear, M.D., Assistant Surgeon 91st Regiment, aged 31, on July 24.

RUSSELL, Robert, Esq., Surgeon, in Mexico, on June 10th. He was attacked by fourteen robbers, and cruelly murdered, after fighting bravely for his life.

STEELE, William Palmer, M.B.Lond., Surgeon to the *Conway* (Royal West India Mail Steamship), third son of William Steele, Esq., of Aberavenny, at Kingston, Jamaica, of a second attack of yellow fever, aged 26, on July 4.

STOKES, John, Esq., of Herne Bay, Kent, at 5, Essex Court, Temple, aged 60, on August 5.

THOMSON, Thomas, M.D., Inspector General of Hospitals, at Belvidere, Tunbridge Wells, aged 77, on August 4.

WRANGHAM, William, Esq., Surgeon, of Wragby, Lincolnshire, aged 44, on July 30.

WRAY, Christopher Wright, M.D., Assistant Surgeon of H.M. 87th Royal Irish Fusiliers, from the fall of an avalanche in one of the valleys of Cashmere, aged 27, on May 15th.

BOOKS RECEIVED.

[*An asterisk is prefixed to the names of Members of the Association.]

CUST, the Honourable Lady. *THE INVALID'S OWN BOOK: a Collection of Recipes from various Books and various Countries.* 12mo. pp. 144. London: 1853.

HOGG, Jabez. *DOMESTIC MEDICAL AND SURGICAL GUIDE.* pp. 156. London: 1853.

PART. *MEDICAL AND SURGICAL POCKET CASE BOOK.* London: 1853.

BOYLE, J. F., M.D. *MANUAL OF MATERIA MEDICA AND THERAPEUTICS.* pp. 801. Second edition. London: 1853.

SKEE, F. C. *THE PREVALENT TREATMENT OF DISEASE.* pp. 68. London: 1853.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

[ADVERTISEMENT.]

THE BRITISH MEDICAL DIRECTORY FOR ENGLAND, SCOTLAND, AND WALES.

TO BE PUBLISHED ON THE 1ST OF JANUARY NEXT, 1854.

PRICE SIX SHILLINGS.

ALL Legally-Qualified Members of the Medical Profession are earnestly and particularly requested to refer to the last leaf of "THE BRITISH MEDICAL DIRECTORY" for the present year, and make the "returns" forthwith as there indicated. By attending to this application *instanter*, the accuracy of the DIRECTORY for 1854 will be much promoted, and its value greatly increased.

The Editors of "THE BRITISH MEDICAL DIRECTORY" feel infinite pleasure in announcing, that in consequence of the unparalleled success of the work, the Proprietors have authorized them to state that ONE-HALF of the PROFITS arising from the Publication of "THE BRITISH MEDICAL DIRECTORY" will be handed over to MR. PROPERT, the Treasurer of the MEDICAL BENEVOLENT COLLEGE, as a Contribution to the FUNDS of that splendid Institution.

The Profession having by their powerful and universal patronage and assistance completely identified themselves with the principles and success of "THE BRITISH MEDICAL DIRECTORY", the allocation of a moiety of the Profits arising from its Publication is made as a free and graceful offering in aid of an Establishment which is dedicated to the noblest of charitable purposes.

The Editors of this Directory consider it right to make the Profession acquainted with the fact that the compilers of "THE LONDON AND PROVINCIAL MEDICAL DIRECTORY" have just made the following admission in reply to a letter of complaint that had been addressed to them by a homoeopathic practitioner: "We have omitted the appointments and the publications, because the profession declared they would not support the 'Directory' if these obnoxious addenda were inserted; but it was contrary to our judgment, and we must admit it was contrary to the professed objects of the 'Directory.' . . . The doctor must look upon us as caterers for the profession, subject to dismissal and defeat if we do not satisfy the appetites, whether depraved or otherwise, of our supporters.—EDITORS OF THE MEDICAL DIRECTORIES."

Thus it is perfectly evident that if "THE BRITISH MEDICAL DIRECTORY" were not in the field, "THE LONDON AND PROVINCIAL MEDICAL DIRECTORY" would again contain descriptions of all the titles, distinctions, and public appointments of all the quacks in the kingdom. The compilers of "THE LONDON AND PROVINCIAL MEDICAL DIRECTORY" even admit that the appointments, titles, &c., of the homoeopaths have been omitted in the last edition of their Directory, contrary to their own judgment and the proposed objects of that work; and then they remark that the homoeopathic practitioner by whom they have been addressed "must look upon them only as caterers for the profession, subject to dismissal and defeat if they do not satisfy the appetites, whether depraved or otherwise, of their supporters."

Now the possibility of a doubt, therefore, cannot be entertained as to what would have been the contents of "THE LONDON AND PROVINCIAL MEDICAL DIRECTORY" for the current year, and of the volumes of that work in future years, had it not been for the publication and extraordinary success of the "BRITISH MEDICAL DIRECTORY." With respect, then, to the different Medical Directories, the confession of the offending parties has made the profession acquainted with its exact position.

Half-a-column	-	-	-	1	10	0
A whole column	-	-	-	2	15	0
A page	-	-	-	5	5	0

A line contains ten words, so that any one can calculate the cost of an advertisement.

Advertisements ought to be delivered at the office on the Wednesday preceding publication, and paid for at the same time.

Post-Office orders are to be made payable to THOMAS JOHN HONEYMAN, 37, Great Queen Street, Lincoln's Inn Fields, London.

A REPORT OF SCIENTIFIC COMMUNICATIONS READ AT THE SWANSEA MEETING was not given, simply because most of the papers will be published in the volume of Transactions, should it be resolved on to venture upon such a work. If the authors desire it, we shall be glad to print the communications referred to, provided no volume of Transactions is to appear: but it would not do to print the same papers both in the Journal and in the Transactions. We trust that this explanation will satisfy those correspondents who have expressed surprise and regret at no report having been given in the Journal of certain very valuable scientific papers read at the recent anniversary meeting.

FINANCIAL STATEMENT. More than one correspondent asks how there can be odd pence in the amount of annual guineas reported as received during a year? We presume this arises from the net sum being stated which was received by the Treasurer, and that expenses were incurred in collection, through the remissness of some members.

PECUNIARY VALUE OF MEDICAL OPINIONS TO LIFE ASSURANCE COMPANIES.

IN the August number of the *Monthly Journal of Medical Science*, is an able and laborious investigation by Dr. Christison of the causes of death in the Standard Assurance Company during five years, ending in November 1850; and no one can read it without being strongly impressed by the vast and increasing pecuniary benefit to such companies of medical experience. It is impossible for a medical referee to determine if a healthy man will not be cut off by fever, cholera, or acute disease; nor can he prophesy whether an invalid life may not be as long as an apparently healthy one: but the increased power of distinguishing diseases which results from the advance of medical science, enables him to state, with an exactness not possible fifty years since, what deviations from perfect health do exist, and thus point out the cases in which an increased premium should be required.

In carefully investigating the medical reports given many years since, on the health of those who have died during this period, Dr. Christison meets with many lives which would not have been accepted in the present day as assurable on ordinary terms. And why? Because our advance in patho-

logy, as well as in the knowledge of symptoms, shews us the more precise value of these symptoms. We now understand better the material causes on which those symptoms depended, and are therefore better able to determine their probable influence on life. It is only by looking back some thirty or forty years, that we can appreciate the improvement in our art which renders our opinions of so much more value to these companies.

Our present more exact knowledge of the diseases of the heart and lungs, owing to the labours of Laennec and his followers; of the diseases of the nervous system, from the physiological discoveries of C. Bell; of the causes of dropsies, and of general decay, from our better acquaintance with morbid anatomy since Dr. Baillie, and especially from the labours of Dr. Bright; and of the connexion between rheumatism and diseased heart, so carefully investigated by Dr. Latham, are a few of the discoveries of modern science which bear on this subject, and which have given to medical examinations a value which it is difficult to estimate sufficiently. For the labours of these discoverers are the common property of all well educated practitioners, and are brought to bear in every town and city and village on the elucidation of those questions on which the prosperity of assurance companies depend. Without the data with which we furnish assurance companies they could not exist. On our reports are founded their true stability, and their hold on public confidence.

The refusal, therefore, of some offices to pay for the report of the medical attendant of the patient is one of the most unwise kinds of economy. It is a principle in the best regulated public companies to remunerate liberally all those who actually work, so as to make them sharers in the prosperity of the great undertaking; and not to screw them down to the lowest point, in order to increase the dividend to an amount perhaps insignificant to any individual shareholder. And this wise and just principle should guide all assurance companies. To withhold the due payment for the most important evidence, in a mere business point of view, is a mistake likely to defeat itself. Here we have abundant statistical evidence that the increased exactness of modern medical science, in distinguishing and detecting diseases, directly increases the profits of assurance companies, by enabling them to charge higher rates on lives which some years since would have been accepted on lower terms; and yet many offices are shortsighted enough to dispense with this evidence from the medical attendant of the assurer (who knows his past history), rather than pay a fee small in proportion to the value of the evidence supplied.

We would urge the shrewd secretaries and actuaries of assurance companies to read carefully Dr. Christison's Report, and to judge for themselves of the importance to the interests of their establishments of obtaining the fullest medical evidence they can command on all the lives submitted to them with reference to this single point. Such a report is also useful to ourselves, in giving a due sense of the value of medical evidence, and consequently of medical certificates. It may seem to the medical practitioner himself but a trifling effort to run his eye over the person submitted to his examination, to examine him physically, and to answer a few printed questions. He may forget the time when such a scrutiny would have afforded him no insight; he may not remember the long course of preparation and of active practice which has made him able to pronounce a safe opinion; nor may he estimate the value of the knowledge he has gained of his patient's constitution. Reports of this kind, which prove that the business foundation of assurance companies rests on medical evidence, and that the increase of their profits and the safety of their risks depend greatly on accurate diagnosis, will tend to strengthen many in their determination to make the offices pay for the most important article they need—the labour of medical men's brains. It may be repulsive, in a strictly scientific sense, to look at these questions in a mere pecuniary view; but the conduct of assurance companies, which are mere trading bodies, forces this upon us.

THE CLUB SYSTEM.

We print, to-day (at page 781), a letter on the "Club System", which conveys, in terse and excellent language, the more important, if not all the enormities of that system, and which wants but one thing—the writer's signature. There is no reason why any man should withhold his name from such a straightforward letter as that of our esteemed colleague, S. T.; and we do hope that, when he again favours us with a communication, he will declare himself as boldly as we do ourselves, and give evidence that he is no supporter of the prevalent opinion, that men in general are more ashamed to be seen performing *good* than *indifferent* deeds.

We are quite prepared to bear witness to the statements contained in the letter before us; and we cannot too earnestly point out to all whom this Journal may reach, the fact, that our Association does possess the power, not only to take up the important question of the payment of medical men by sick clubs, but to remove many—perhaps every one—of the evils connected with the system. The subject, we imagine, comes within the sphere of the medico-ethical committee appointed at Swansea.

Our correspondent has hit upon the right mark, when he says, that "the founders and conductors of such societies (clubs) are not ignorant of what ought to be proper professional remuneration; only they are tempted, for the sake

of showing a flourishing balance sheet, to commit the injustice, and medical men are foolish enough to submit." This, we reassert, is the secret cause of all the mischiefs that occur to the profession through club appointments. The penny wise and pound foolish practice is one which the world will be a long time in discarding, even in the matter of private family concerns; and much longer in public affairs. For, in conducting the latter, another mental element, *vanity*, comes into play. The conductor of a club follows, in his small way, like an Indian scout, in the very footmarks of him who in his great way conducts the affairs of the republican or free monarchical government. To stand well in the eyes of the governed; to catch from their unloosened tongues the magical words, "hear, hear"; to receive from them a vote of thanks, increased in value, it may be, by a vote of unoxidizable metal, are the great objects of almost every man who stands at the head of a public institution, be it little or great. And to obtain these distinctions, the penny wise and pound foolish system is, as a general rule, the best card to play; for, say what one will about the blessings of health and such like matters, the blessings of money are with nine out of ten of the multitude those for which they in their hearts most crave.

We wish it to be understood, however, that we are not advocating the introduction of a system of extravagance into sick clubs. We would as soon think of advocating the abolition of such societies, while we recognize in them principles of great and lasting value. But it is our impression that these societies need considerable and immediate reform.

Our correspondent tells us that the publicans inflict great injustice on medical men, by securing attendance on the club principle whilst they are well able to pay a fair doctor's account. This leads us to state, that one very useful reform in sick clubs would be altogether to remove them from the influence of publicans and public houses. A club might be held in *its own rooms*, at a much cheaper rate, and in a much more reputable way, than in any public house in the kingdom. Connected with such clubs, reading rooms, self educating classes, and constant friendly and *sober* intercourse might also be established.

In country districts, we know that medical men have often considerable influence in the management of clubs and friendly societies; and we throw out the hint to them, that they would act in a manner worthy of their humanising mission, were they to instil into the minds of their poorer brethren, the idea that it is neither essential to happiness nor to the success of a friendly institution to have meetings amongst volumes of tobacco smoke, and in houses from which scenes of debauchery are rarely absent.

In reforming the "Club system" as in all other matters of medical polity, our Association can exert great power; and now that the subject has been so well brought forward, we trust that the evils which have been pointed out may be speedily removed.

ORIGINAL COMMUNICATIONS.

EXAMINATION OF DIFFERENT OPINIONS AS TO THE VALUE OF THE CLIMATE OF MADEIRA IN CHEST DISEASE.

By GEORGE LUND, M.D., of Funchal, Madeira.

REMEDIAL agents used in the practice of medicine have, in all ages, had various degrees of importance attributed to them. In some cases, the assumption of the almost infallibility of newly introduced medicines in effecting cures has gradually led to their disuse; for, the exaggerated promises of the recommender not being fulfilled, the opposite view has become general. Thus, unmerited neglect has often been thrown upon many really useful adjuncts of the remedial art, which, highly beneficial when applied in proper cases and under right circumstances, have failed when used improperly; the error being unjustly attached to the remedy, and not, as it ought to have been, to its misapplication. The generality of mankind are too apt to look to specifics for the cure of ailments, overlooking the fact that diseased action rarely continues long the same. The products of diseased action, as effusions, depraved secretions, etc., often become themselves the disease to be treated, the primary state having ceased or changed. We thus ascertain that no one remedy can be universally applicable to the varying phases of a disease; and although it may be, and often is, an essential link in the chain of treatment, it can be correctly viewed only as contributing its subordinate though necessary help in assisting the whole means used, and aiding the natural powers to throw off diseased action, and thus ensure a return to healthy function.

Climate appears at the present time to be placed much in the position of the remedial agents just alluded to; at one time being too highly estimated, and by many looked upon almost in the light of "a cure", which necessarily has led to disappointment. Such an extravagant expectation not being realised, the idea has gradually spread that climate has little or no effect as a remedial agent, and its undue depreciation has thus ensued. Hence, in this as in many other cases where opinions differ, we shall find that a middle course is nearest akin to truth; and that by following it we shall not be so far misled, as others who adopt extreme views. No one personally acquainted with the effects of a well selected climate in disease can deny its great efficacy in many complaints, especially in various chest diseases, and in consumptive cases, when these are sent out in an early stage, and the patient behaves with common prudence. Unfortunately, such favourable results induce a host of most unsuited, often literally dying people to try this remedy, of course for the most part unsuccessfully; and then climate is declared by the surviving friends to be a useless agent. To such an extent had this influx of unsuitable cases arrived at one time in Madeira, that the late Dr. Renton published a paper, pointing out the great evils of the practice, and forcibly showing the inutility and cruelty of sending far advanced cases abroad, in the vain hope of recovery,—a remonstrance which, for some time, had the beneficial effect of preventing such indiscriminate abuse of climate.

The beneficial effects of Madeira in suitable cases are well known to the resident medical men; but, to ensure favourable results, the invalid must shew prudent conduct and follow hygienic rules. Such persons generally do well; and there is no doubt that many, who would have been in their graves if they had remained in a variable climate, have been restored to their friends by a temporary residence in one more genial, where, while avoiding most of the exciting causes of lung disease, they could invigorate the general health by means not available in England during the winter and spring months; thus enabling the system to throw the tubercular materials out of the blood, if they exist only there, and, if deposit has already ensued, to keep it unirritated and unsoftened, and so to arrest the onward progress of disease. I have witnessed, in cases very recently

landed, and where the physical signs have been exceedingly slight, rapid and extensive tubercular deposit ensue in the lungs from excesses combined with imprudent exposure to the midnight air. Slight catarrh has come on; and this fixed irritation has appeared to be all that was necessary to cause a rapid accumulation of the deposit in the lungs. Had there been no imprudence, and no lung irritation, in all probability the consumptive materials might, in the course of time, have been safely eliminated from the system, without being deposited in the lungs.

It is greatly to be regretted that much of the benefit of climate is entirely lost, from the imprudent conduct of many who come out, and act as if climate were to do everything, themselves nothing. These persons, content at home, and, whilst under the watchful eye of anxious relatives, considered and acting as invalids, on becoming their own masters abroad, throw off all previous restraints, freely indulge in various imprudencies, and, when their disease has gained ground, declare (in Madeira at all events) that their impaired health arises entirely from "the relaxing effects of the climate". Of these alleged effects their friends and doctor at home are duly informed; nothing, however, being said of late dinners, evening parties, dances, concerts, cigars, and stimulants of various sorts, etc.; these, of course, not having in their opinion aided in breaking up the general health.

The leading members of the medical profession give sufficient evidence of their favourable opinion of climate, by recommending their patients to avail themselves of its benefits. In confirmation I shall quote the opinions of Sir J. Clark and Dr. C. J. B. Williams, and shall afterwards investigate the grounds upon which an unfavourable opinion has been advanced by others.

Dr. C. J. B. Williams writes thus: "Under treatment and favourable circumstances of air and climate, these symptoms and signs have been gradually removed, in some cases entirely, in others partially, but to such an extent, that the patient's health has been in a great degree restored. It may perhaps be said, that we have no certain proof that these cases were phthisical, or, if they were so, that the phthisical lesions were entirely removed. I admit this, but maintain that the existence of phthisis was as much proved as it ever can be in its early stage—that precisely similar cases, when neglected, commonly run a consumptive career; and we are not aware that such a combination of signs and symptoms can be produced but by lesions, which essentially have a phthisical tendency."

Dr. Mackness, quoting Sir J. Clark, writes: "A cold, damp, and variable climate not only gives the predisposition to this disease (*i.e.* consumption), but becomes its exciting cause, and determines in an especial manner its local manifestation in the lungs. While, therefore, invalids thus predisposed continue to reside in a climate which fosters their disease, but little relief must be expected from any medical treatment, however judiciously employed. It becomes an imperative duty for physicians to advise such patients to resort to a more genial climate."

Sir James Clark thus proclaims his opinion: "The influence of climate over disease has been long established as a matter of fact; and physicians have, from a very early period, considered change of climate and change of air as remedial agents of great efficacy. This opinion is supported both by reason and experience. From the application of climate to unsuitable cases (*i.e.* its misapplication), and the resorting to it as a last resource, it need not excite surprise that success has not more generally attended the practice of sending invalids abroad; nor even that the result should have been such as to bring the remedy into discredit. The fault, however, is to be sought for, not in the remedy, but in the manner in which it has been applied." Sir James Clark then states his conviction, that we possess in change of climate, and even in the more limited measure of change of air in the same climate, one of our most efficient remedial agents, and one, too, for which in many cases we have no adequate substitute.

The late Dr. Andrew Combe, so well known by his pub-

lications on the subject of preserving health, was most earnest in always inculcating and practically demonstrating the importance of hygienic rules for the preservation and restoration of health. Climate was always ranked by him among remedial agents of high efficacy, and he carefully secured its advantages in his own case; for, in writing to a friend, after having resided in Madeira, he says, "If I must go abroad, I shall most likely return to Madeira, simply on the ground that, if I must forego the pleasures of home, it is better to resort at once to the *most advantageous* climate, than to adopt the half measure of going to Italy, Jersey, or the south of England." (White's *Madeira*.) When in Italy, Dr. Combe considered the climate as unsuited for invalids in an advanced stage of disease, though he did not take such an extreme view as Dr. Burgess, a recent author on the climate of Italy, who declares change of climate in disease to be a delusion. He (Dr. Burgess) writes, "There is no greater popular delusion than the belief in the existence of some undefinable specific virtue in the climate of Italy for pulmonary consumption. This 'foreign climate delusion' is not confined to the rich invalid;" he adds "it is only when the disease is confirmed, and softening exists, that, in the great majority of instances, the patient seeks in a foreign climate that relief or cure, which he believes nature has denied him in his own."

Sir James Clark has clearly explained that climate is not beneficial in such unsuitable cases; and that to use it only as a last resource is merely to abuse a remedial agent of acknowledged efficacy. When it is properly used, and under the most favourable circumstances, the invalid is to remember that the change only places him in a better position for the hygienic treatment of his disease; and that, without prudence and self-control on his part, little good will ensue from mere change of locality. The idea of climate being a cure for phthisis, Dr. Burgess says, is "a popular delusion". It is to be hoped that no medical man of the present day ranks it higher than a curative agent of great efficacy when properly applied. He remarks, in continuation, that the influence of climate on health and disease has of late attracted considerable attention; hence, instead of vague assertions or traditional fame, authenticated facts are essentially requisite to establish the sanitary character of any given climate. At the end of his preface, Dr. Burgess concludes thus: "Although several of the subsequent statements may be opposed to various popular notions prevalent in England, no opinion has been hazarded without the support of positive data; consequently, readers can judge whether the conclusions I have enunciated are fully warranted by the evidence upon which they are virtually founded." Fully admitting the importance of these remarks, and the great desirableness of receiving only well authenticated facts, I shall proceed, in compliance with Dr. Burgess's request, to ascertain whether or not his conclusions with respect to the climate of Madeira are erected on such a foundation as to warrant his readers in receiving them as correct.

Amongst other remarks, I shall test the following: "That the popular faith in the virtues of this climate in pulmonary consumption is founded, for the most part, on tradition and romance; that, in short, the climate of Madeira, as regards the cure of phthisis, is as great a delusion as the climate of Italy." This is strongly put, and in forcible language; but I hope to give sufficient proof that, while the Madeira climate does not fulfil the popular delusion of being a cure, it is an agent of great curative efficacy in aiding proper treatment.

Dr. Burgess, having no personal knowledge of the island, of its climate, or of the results of cases sent out, forms his opinions from two works, viz., White's *Madeira*, and Dr. Mason's *Treatise on the Climate and Meteorology of Madeira*; and from the latter, the opinions of the late Drs. Heiniken and Gourlay are incidentally brought in. Mr. Harcourt's book on Madeira, published by Mr. Murray at the time when Mr. White's came out, is not mentioned; his opinion is in favour of the climate. Dr. Burgess first quotes from White's *Madeira*; but, before proceeding to examine the

extracts he has made, I may remark, that Mr. White is described as enthusiastic in his praises of Madeira, and grateful for restored health. Any one having the pleasure of being acquainted with Mr. White must be well aware that he is not of an enthusiastic disposition, and that he is peculiarly well qualified to afford correct information concerning Madeira, for the following reasons, viz., a residence of more than fifteen years on the island, his acquaintance with the people and their customs, and correct knowledge of their language. It is pleasing to find Dr. Burgess recording Mr. White's gratitude for restored health, attributed entirely to his sojourn in Madeira; and it is equally gratifying that I am enabled to add, that he is now living in continued good health in his native land—one out of many proofs of the good effects of climate.

In the quotations which Dr. Burgess makes from Mr. White's book, he writes, that Mr. White is obliged *reluctantly* to make the following confessions:

1st. That pulmonary consumption and scrofula do occur, but *less frequently* than in more changeable climates.

2nd. That there are different eddies or currents caused by the vicinity of mountains, which render a vane or anemometer of little use.

3rd. That the sky is not so clear, nor the atmosphere so calm, as in Italy.

I shall consider these remarks in the order in which they are placed above.

First, with regard to the statement "that consumption and scrofula do occur (in Madeira), but *less frequently* than in more changeable climates." To proceed with Dr. Burgess's extract: "Mr. White, a non-medical writer on the subject, is enthusiastic in his praises of the climate, and evidently grateful for the blessing of restored health, which he attributes entirely to a sojourn at Madeira." He (Mr. White) "remarks, without advancing any pretensions to medical knowledge, or the physiological effects of climate, that a residence of many years at Madeira, and a lengthened pursuit of health among the most favoured localities of Europe, enable the writer to add his testimony to the decided superiority of the climate of Madeira over all those he has visited. Cold winds, or close, sultry weather, are little known: and a continuous summer may be enjoyed, without suffering from extreme heat or cold, or a continuance of damp or wet weather. The most remarkable feature of the island is probably the mildness and equability of its climate, and its consequently beneficial effects in pulmonary and other complaints." Dr. Burgess remarks upon the preceding, "Notwithstanding this eulogium, the writer (Mr. White) has some misgivings as to the perfection of the climate, and reluctantly admits that, though so 'very equable', the climate of Madeira is not altogether free from changes, which constitute there, as well as elsewhere, the exciting causes of pulmonary affections. Pulmonary consumption and scrofula occur among the natives of Madeira, but *less frequently* than among the natives of more changeable climates." Upon referring to Mr. White's book, chapter ix, it appears that Mr. White is not the author both of the eulogium and subsequent misgivings as to the equability of the climate; for it is expressly mentioned, that the following brief remarks were obtained from one of his medical friends, who gives his opinion thus: "Although the climate of Madeira is so very equable, it is not altogether free from changes which constitute here, as well as elsewhere, the exciting cause of pulmonary and inflammatory affections." Dr. Burgess omits the following, which follows in continuation: "These, however, as may be supposed, are comparatively rare among the better classes, and occur chiefly among the hardworking poor, who are more exposed to this cause, and to sudden chills of the surface while perspiring profusely. An epidemic catarrh not unfrequently makes its appearance about the months of August and September, or before the annual rains which usually occur in October. It is now pretty well understood, that no climate affords entire exemption from scrofulous diseases. Whenever the exciting causes are applied,

in whatever part of the world, these diseases manifest themselves. Pulmonary consumption is connected with what is called the scrofulous diathesis, and occurs among the natives of Madeira, but prevails much less among them than it does among the natives of more changeable climates." That it should occur is not to be wondered at, when we find many of the causes of the scrofulous diathesis in full operation among a large proportion of them, viz., imperfect food and clothing, deficient ventilation of their low, damp huts, combined with overwork.

A short extract, like the one made by Dr. Burgess, seldom affords a clear insight into an author's meaning; and I trust that, by supplying the sentences entire and unmutated, the writer's real meanings have been placed in a more distinct point of view; and that, being so viewed connectedly, they simply show the well known and acknowledged fact, that *causes* of disease, such as imperfect food, scanty clothing, deficient ventilation, damp wet dwellings, joined to overwork, do exercise their baneful influence in Madeira, as elsewhere, but with this important limitation, that they do so with less effect than in other places; that scrofula and consumption occur among the natives of Madeira, but *less frequently* than in more changeable climates. The diseases attributed to the changes in the weather are especially noted in Mr. White's book to be "pulmonary and inflammatory, chiefly occurring amongst the poor hard-working people, from sudden chills causing checked perspiration."

The second quotation extracted by Dr. Burgess is also imperfect, from beginning in the middle of a sentence. It is thus given: "Yet, in this almost perfect climate, the same writer (Mr. White) informs us that the different eddies or currents render either a vane or anemometer of little use." The *entire* sentence gives the reason: "From the position of the basin of Funchal, open only towards the south, it is difficult to ascertain the true course of the winds, and [here Dr. Burgess only begins] the difficult eddies or currents caused by the vicinity of mountains render either a vane or anemometer of little use."

Dr. Burgess's third quotation is to the following effect, "That the sky cannot be generally so clear, nor the atmosphere so calm, as that of Italy, from the position of the island, and nature of its surface." I again supply the whole sentence, as the extract begins in the middle of one, after a comma: "From the position of the island of Madeira, and the lofty and rugged nature of its surface, it will appear sufficiently obvious to every one conversant with the causes of the formation of clouds and the trade wind [here Dr. Burgess commences the extract], that the sky cannot be so clear, nor the atmosphere so calm, as that of Italy." Mr. White proceeds: "The preceding tables, however, though compiled during a season of unusual severity, certainly one of the coldest for a great number of years, still afford a favourable result."

We subjoin Mr. M'Ewen's table of the comparative appearance of the sky, from Dr. Mason's work, and quoted by Mr. White:

Blue or clear sky, . . .	240 times.
Cloudy,	223
Hazy	30
Overcast,	30
Threatening,	19
Rain,	13
Showers,	11
Fogs (none)	0

566 observations.

Thus, showers or rain fell twenty-four times in 566 observations. The clouds rarely descend lower than the Mount Church, an elevation of more than 1,800 feet; and form a most necessary and agreeable screen from the sun's rays.

The atmosphere is stated by Dr. Burgess not to be so calm. I append the following table in refutation:

Calm,	102
Light winds,	130
Fresh winds,	82
Strong winds,	9
Presumed gale,	1

324

So that, out of three hundred and twenty-four observations in this climate, alleged to be deficient in calmness, we find only nine strong winds, and one presumed gale.

Dr. Burgess gives, on the authority of Dr. Mason, the following quotation, with reference to the variability of the weather at Madeira, and adds, that it will perhaps surprise his readers. If the reader has ever resided at Madeira, we think he will be astonished at the following statement: "The very frequent and remarkable variations in a series of years, incontestably prove that Madeira is no more to be relied on than any other place for certainty of fine weather; and that it has equally its annual variations of temperature." Dr. Burgess's own opinion as to the requisites in climate for an invalid is as follows: "It is not heat, but equality of temperature, even if it were at a low range, that is needed by the class of invalids referred to; and, whenever an approximation to that quality of climate can be found, there should the consumptive invalid reside." I quite agree with Dr. Burgess's opinion, that equability is an essential element in any climate used for invalids with delicate chests; and I think that Madeira supplies that desideratum, in addition to having home comforts which most other foreign places of resort sadly lack. Certain I am, that changes injurious even to delicate persons do not occur there, and that the most sensitive invalid need never suffer more than a temporary feeling of discomfort. True it is, that invalids often ascribe their various ailments to the effects of climate, which would be more justly ascribed to their own frail bodies, and to the usual complications of disease.

As to the variability of the Madeira climate, alleged by Dr. Mason to exist, we extract the following, to show that other observers do not (as in other observations) confirm his opinion. Sir James Clark, on the authorities of Drs. Renton and Heiniken, both scientific men, and many years resident on the island, writes thus: "When we take into consideration the mildness of the winter, the coolness of the summer, together with the *remarkable equality* of the temperature during the day and night, as well as throughout the year, we may safely conclude that the climate of Madeira is the finest in the northern hemisphere." The winter at Madeira is 20° warmer than at London, and has no fogs; the summer is only 7° warmer, and is free from the oppressive closeness so common there. "No one", writes Sir James, "need breathe, night or day during winter, a lower temperature within doors than 64°, or in the country 74°." That is only ten degrees of mean difference of Fahrenheit between summer and winter; whereas a summer day in England has often greater changes. The following tables show how little variability of temperature there is; two of the years' observations having been made nearly one hundred years ago:

Date.		1847.	1749.	1750.	1850.
January	59-50	57-71	63-50	—	64-00
February	58-50	60-28	63-14	—	63-80
March	61-06	61-86	64-22	64-66	66-50
April	62-50	63-03	64-40	66-07	66-47
May	63-50	63-44	64-76	66-53	66-25
June	65-00	66-90	68-72	68-75	69-06
July	70-00	70-04	72-50	74-58	73-00
August	73-00	71-88	73-58	75-07	75-40
September	71-50	71-28	71-94	76-53	74-93
October	67-50	66-76	71-06	72-20	73-87
November	62-70	63-96	67-64	68-60	70-82
December	60-50	61-44	63-86	64-90	66-27

Authorities: Sir J. C. White, Harcourt. Mr. White.
(Interval of a century.)

Sir James Clark states the mean annual temperature of Madeira to be 64° 56' Fahr.; the mean difference between

summer and winter, $9^{\circ} 38'$; mean difference between the coldest and hottest months, $14^{\circ} 50'$; the mean difference between successive months, only $2^{\circ} 41'$; differences between winter and spring, $2^{\circ} 70'$; between spring and summer, $7^{\circ} 13'$; between summer and autumn, $2^{\circ} 10'$; between autumn and winter, $7^{\circ} 73'$. The differences of successive months are: between January and February, 1° ; between February and March, $2^{\circ} 56'$; between March and April, $1^{\circ} 44'$; between April and May, $0^{\circ} 50'$; between May and June, 2° ; between June and July, 5° ; between July and August, 3° ; between August and September, $1^{\circ} 50'$; between September and October, 4° ; between October and November, $4^{\circ} 80'$; between November and December, $2^{\circ} 20'$; between December and January, 1° .

Mr. Harcourt, writing from his personal experience of the climate, gives his opinion as follows: "The mean temperature of Funchal throughout the year may be stated at 66° Fahr.; February and March being the coldest, August and September the hottest months. Even between these months there is not a greater mean difference of temperature than 12° . It is this uniformity in which the excellence of the climate consists. The causes which are instrumental in forming such a climate in Funchal are threefold: 1st. The lofty hills, which immediately surround it on the north, completely shelter it from the weather at all points of the compass except from south-east to south-west. 2ndly. The absence of wood, while it impairs its beauty, improves its climate; and 3dly, the regularity of the alternations of the land and sea breezes tends to preserve a delicious equality of temperature."

"This climate is certainly fine enough to please even fastidious people. A range of 12-14 degrees between summer and winter, surely does not amount to 'frequent and remarkable variations'; and even this small amount of difference between the hot and cold months may be greatly, and almost entirely, avoided, by going out of Funchal during the summer, which it is the custom to do. In the mountains the summer heat is less than in England; but, at this elevation, there is too much damp for an invalid, though healthy persons enjoy such mountain air, and are braced by it. Lower down the air is drier, and an invalid can have summer with the thermometer rarely exceeding 72° or 74° ." In the Isle of Wight, the most favoured of English places for consumptive persons, the difference between the hot and cold months is 28 degrees, being fully double what it is at Funchal.

I shall now proceed to investigate the extracts in Dr. Burgess's book, taken from Dr. Mason. Before, however, detailing the results of Dr. Mason's observations, Dr. Burgess informs us, that the instruments used were improperly placed, a fact which alone vitiates the whole of the results. The instrument chiefly used was the hygrometer, which is very easily affected by the slightest causes, arising from local currents of air, moisture, or ill-chosen locality: and it is much to be regretted that so much zeal and industry as the late Dr. Mason exhibited, should be rendered of no avail, not from one, but from many causes of inaccuracy. Dr. Burgess says: "I shall now place before the reader the leading facts contained in Dr. Mason's book"; and a little farther on, "a summary of Dr. Mason's observations will enable the reader to form his own opinion as to their merits, and the reliance to be placed on them." Mr. White, as usual, explains matters more fully and correctly. He writes: "The situation, where Dr. Mason's observations were made, is notoriously one of the least favourable for that purpose in the outskirts of Funchal; and this circumstance, together with the fact of his hygrometer being placed in a close room, between two windows, near an open tank, and surrounded with trellised vines and vegetation, independent of the acknowledged severity of the season during which they were made, will sufficiently account for the difference existing between his observations and those of other parties." Independently of other sources of error, the immense exhalation from the leaves of plants would vitiate hygrometrical observations. An experimenter, placing his instruments in a place which has marked peculiarities, can obtain only

results appertaining to that locality, and cannot correctly affirm, that observations thus made truly indicate the general climate of a country. No one would place an hygrometer in a Lincolnshire fen, or an Irish bog, to decide the general humidity of the climate in either country; nor can more weight be justly allowed to Dr. Mason's observations, than that they indicate the humidity of the atmosphere near his own water tank. At one time it was thought that the greater humidity observed by Dr. Mason must have originated in the observations having been made in a damper season than usual; but this opinion is apparently erroneous, because the year in which they were noted, 1834-5, was a particularly good wine year, and, to secure a good vintage of full flavour, a dry season is necessary; consequently we must look to other sources for the discrepancies observed between his remarks and those of other persons. On the island, it is well known that the locality is damper than the neighbourhood around it; but the accuracy of the whole series of observations is vitiated chiefly from the improper position of the instruments, etc. Dr. Mellermair, who has made careful observations, informs us, that the results obtained by him confirm Mr. White's, and that both prove Dr. Mason to have placed the humidity of Madeira one-third too high.

The following letter from Mr. Wilkinson of Madeira more fully explains the above:—

"Funchal, 1st June 1853.

"SIR,—In reading the book on Madeira, by Dr. Mason and Mr. Driver, edited by Sheridan Knowles, the suspicion occurred to me, that the conclusions there made with regard to the climate of the island, and drawn from the meteorological tables said to have been kept by the late Dr. Mason, were not trustworthy.

"I was personally acquainted with the late Dr. Mason, and had the pleasure of enjoying a good deal of his society while he resided in Madeira; and I know he did not reside at Sta. Luzia during the whole time the tables are given as having been kept there by him, but that he made frequent and long excursions into the country. Neither, to the best of my recollection, did he leave any one to carry on the tables during his absence. True, he always carried a small thermometer and hygrometer with him into the country; but that could have nothing to do with observations on the climate of Funchal or its neighbourhood.

"When Dr. Mason commenced his observations on the temperature, etc., of the atmosphere here, it was solely, I believe, to assist him in some improvements he was attempting in hygrometers; but, at the same time, he noted down his conclusions with regard to the value of the climate in the treatment of disease. Certainly his means of arriving at these conclusions were very imperfect. His attention was chiefly directed to the working of a Leslie's hygrometer, and of a common thermometer, hung in a cupboard. All this, of course, casts no imputation on Dr. Mason; as Mr. Driver and the editor of the book are alone answerable for the use they have made of the imperfect notes left by that gentleman at his death.

"Another circumstance, that would make his observations of little value for hygrometrical purposes, was the situation in which his instruments were placed; viz. a corridor about eight feet from the ground, and about fifteen feet from a tank holding about three hundred gallons of water. The water in the tank was renewed about every fifteen days, by a stream running into it; but was never entirely emptied, as it contained fish. The tank is of stone, entirely open at the top, and nearly on a line with the corridor. The surface of the water lies exposed to the afternoon sun, and to the current of air from the valley of Sta. Luzia. In fact, no one, who had a choice, would choose such a situation for purely meteorological purposes.

"All this is matter of personal knowledge with me; and you will easily understand why I should be of opinion that the late Dr. Mason, had he lived, would never have published his notes in the form we find them in this work.

"I remain, sir, yours truly,
"G. LUND, Esq., M.D."

"SAMUEL WILKINSON."

The objections made to the climate of Madeira, on the authority of Dr. Mason, may be classed under the following heads:—dampness, rains, injurious effects of the l'este, and precipitation of dew.

It is mentioned that London, at its mean temperature of 58°, can contain 100 parts of moisture; whilst Funchal, at 68°, can hold 200. Both calculations being made by Fahrenheit's thermometer, commence at the freezing point, 32°; add 18°, and we have the London temperature; double the temperature by 18° again, and we get 68°, the Funchal temperature, simply shewing that double the heat and double the quantity of moisture will be suspended in the atmosphere. Further, in Madeira it is suspended, and is never visible in the shape of fogs, except on the mountain tops.

Mr. Harcourt thus expresses his opinion on the alleged damp of Madeira:—"Whatever may be the moisture of the air, it is not sensible as dampness to the feelings, and certainly is not unfavourable to the healthy action of the lungs. There may be spots in Madeira, either near yam grounds, where much irrigation is carried on, or where the soil and rock, usually very porous, are so close as to retain the wet, which may be too humid for some constitutions; but, for the greater part, in the neighbourhood of Funchal, there is no visible excess of moisture, there is no fog, and there is comparatively little dew. If dampness has ever been alleged as an objection to the salubrity of this island (Madeira), it must be regarded as a complaint due to the unlucky choice of some dwelling house unfavourably placed, or to the common fastidiousness of ill health."

Dr. Mason pronounces Dr. Heiniken in error, for stating "that at the level of the city of Funchal, no perceptible dew is produced, but up the mountains it is profuse."

It is surprising how Dr. Mason could have committed such a mistake; for every resident is well aware that Dr. Heiniken is in the right, and Dr. Mason glaringly in the wrong. Sir J. Clark gives the following direction:—"Invalids particularly sensitive to humidity, are recommended to live within the limits of the town, on account of its greater dryness." Again, Dr. Mason makes the following erroneous statement:—"That, on a clear night, the quantity of dew precipitated is so great, that in a few hours many drachms of fluid may be collected." This is palpably incorrect, the experiment having been often tried in other localities, without the plate being even damped.

The l'este, a warm wind from Africa, which is not common, is described by Dr. Mason as injurious in its effects: he says that at one time it made him very well, and at another very ill. We presume that this opinion is of no more value than as it denotes the morbid feelings of a nervous invalid. The l'este does not occur every season, and is felt to produce only temporary inconvenience, and that in summer, when few invalids remain on the island: its general continuance varies between three and six days. Never having had to prescribe for any one made ill by the l'este, I conclude that Dr. Mason has overrated its bad effects. Dr. Mason corroborates the opinion of Dr. Gourlay, as to the frequency of phthisis amongst the Madeirans: the relative value of these may be gathered from the following. Dr. Mason did not speak the language of the people whose diseases he affirms that he knew, nor did he practise amongst them; consequently his opinion must have been secondhand. Dr. Gourlay did practise amongst the Portuguese, but before the stethoscope was used on the island; consequently his means of detecting chest disease must have been very imperfect. The late Dr. Renton, an excellent physician and good stethoscopist, writes:—"With respect to the question relative to the frequency of consumption among the natives, Dr. Gourlay, if he alluded to tubercular disease, has greatly overrated it." Dr. Heiniken also says:—"It has been asserted that no malady is more prevalent than phthisis with the natives of Madeira; but, so far as my own personal experience and the result of inquiries go, I incline to a contrary opinion." (Clark.)

Dr. Burgess thus sums up:—"Madeira, with all its sanitary fame, is no exception to this rule"—that is, it affords

no proof of salubrity, or of the beneficial effects of climate,—"as (to pursue the quotation) the meteorological observations of Drs. Heiniken, Gourlay, and Mason, incontestably prove." Setting all other considerations aside, we do not think that these three observers bear out this assertion in their own cases. Dr. Gourlay was not consumptive. Dr. Heiniken was originally sent out as a dying case, lived nine years on the island, and ultimately died from accidental exposure to the night air in an open boat, when returning from an adjacent island. Dr. Renton opened the body, and was astonished to find how little lung he had left. Dr. Mason, notwithstanding his neglect of means for preserving or obtaining health, and devoting himself instead "most assiduously to meteorological observations", lived in Madeira two years, this time being the full average duration of the whole different stages of phthisis in England. After this, he went to Nice. We are informed that he first visited Madeira with the belief that he would recover his health, under the alleged sanitary influence of that climate. Whilst there, he most assiduously occupied himself in meteorological investigations. From this, the conclusion Dr. Burgess arrives at is, "that the climate of Madeira, as regards the cure of phthisis, is as great a delusion as the climate of Italy." Previously, we were informed that the idea of cure was a popular delusion; but this shews its adoption by at least one medical man. The belief of medical men generally is, that no climate can cure; but that it is an essential and important aid of other means of treatment, which cannot be so efficiently carried on in a variable climate, especially during the winter and spring months.

Dr. Mason, it is stated, always felt persuaded that Nice was a place better adapted to his case than Madeira. Why he remained at Madeira two years, the ordinary duration of a consumptive case in England, with this impression on his mind, and of course, in his opinion, losing vital time, is not explained. Dr. Burgess continues:—"The fate of the author was a melancholy one, and a telling comment on the blind credulity which prevails respecting the virtues of foreign climates in pulmonary consumption." During his journey to Nice, he travelled twenty-four consecutive hours in a diligence, his only sustenance, during that period, being fruit and bread, *accidentally* obtained on the road: upon arriving, dysentery (it is said) attacked him, and proved fatal in a fortnight. Dr. Burgess remarks on this catalogue of imprudences, committed by a dying invalid:—"How many consumptive invalids have fallen victims abroad to the same delusion!" In my opinion, the delusion would have lain in expecting any other result than what happened. Over-fatigue, with improper food, in an advanced stage of consumption, produced the usual diarrhoea (not dysentery), and speedily proved fatal; nor, in fact, could any other termination be looked for.

We have now to consider how far the assertion is correct, "that the popular faith in the virtues of the Madeira climate, is founded for the most part on tradition and romance." The following tables, I think, prove the contrary, and shew that climate, in the majority of cases, saves the life of consumptive people, when they are sent out in the early stage, and before the disease has worked irreparable mischief. The tables of confirmed phthisis speak for themselves.

Dr. Renton's Tables, extracted from Sir J. Clark's work on Climate.

TABLE I. CASES OF CONFIRMED PHTHISIS, 47.

Died within six months after landing in Madeira.	32
Went home in summer, returned and died	6
Left the island, of whose death we have heard	6
Not since heard of; probably dead	3

47

TABLE II. WITH TUBERCULAR LUNGS, 56.

Died here	30
Left the island	22
Still here	4

56

TABLE III. INCIPIENT PHTHISIS, 35.

Left the island, much improved . . .	26
Improved, but not since heard of . . .	5
Have since died . . .	4
	35

TABLE IV. THREATENED WITH PULMONARY DISEASE, 108.

Remained free from symptoms . . .	93
Fell off . . .	13
Lost sight of . . .	2
	108

Table by Dr. Lund, from White's Madeira, shewing the number of patients, in 100 cases of Consumption, landed in different stages of the disease, in whom it was arrested, progressed, and proved fatal.

FIRST STAGE: 48 CASES.

Arrested—37.	
Duration of arrestment.	
From 4 to 10 years . . .	13
For 3 years . . .	2
From 8 to 20 months . . .	11
From 7 to 12 months . . .	11
	37

Relapses occurred in 2 cases.

Progressed—11.	
Living.	
Passed in 14 months into third stage, and slowly progressing . . .	3
Passed in 16 months, 2 years, and 5 years respectively, into second stage . . .	3
	6
Died.	
Died 5½ months after landing . . .	1
Remained one winter at Madeira, and died the next winter abroad . . .	1
Went out for 7 winters, and then died . . .	1
Remained nearly 8 winters, and then died . . .	1
Remained 1 winter, returned home, and supposed dead . . .	1
	5
	11
	48

SECOND STAGE: 24 CASES.

Arrested—5.	
Duration of arrestment.	
Arrested for 15 months; relapsed, and passed into third stage. Disease again stopped for 3 months; general health as good as before the last attack . . .	1
For 15 months . . .	2
For 5 years . . .	1
Came out about 10 years ago; relapsed in 1847: disease again arrested, and continues so . . .	1
	5

Progressed—10.

Living.	
Much ameliorated . . .	2
Still remain in the second stage; but the disease is slowly gaining ground . . .	4
In the third stage: but the disease is arrested, and general health is good . . .	2
	8
Died.	
Remained one winter; and, having left the island in a sinking state, supposed dead . . .	1
Remained one winter at Madeira, and died the next winter at home . . .	4
Died at home, 8 months after first landing in Madeira . . .	2
Ditto, 10 months, ditto . . .	1
Ditto, 12 months, ditto . . .	1
Died at Madeira, 14 months after first landing . . .	1
Ditto, 4 years, ditto . . .	1
	11
	19
	24

THIRD STAGE: 28 CASES.

Arrested—5.	
Duration of arrestment.	
Remained so for upwards of 12 years . . .	1
For 8 years . . .	2
Left the island after 3 years . . .	2
	5

Progressed—28.

Living.	
Arrested for 14 months, and then began slowly to progress . . .	1
Has progressed slowly for 15 months . . .	1
Remained one winter, and then left, their only symptoms being moderate morning cough and expectoration . . .	3
	5
Died.	
Died 48 hours after landing . . .	1
" 6 weeks " . . .	1
" 7 " " . . .	1
" 9 " " . . .	1
" 3 months " . . .	3
" 3½ " " . . .	1
" 4 " " . . .	2
" 5 " " . . .	1
" 6 " " . . .	1
" 7 " " . . .	2
" 10 " " . . .	1
Died 15 months after first landing in Madeira; went home in summer, and died 9 months after returning . . .	1
Died 4 years after first landing . . .	1
Came to Madeira 18 years ago, and remained 7 winters; went home for 3 years; returned to Madeira for 3 winters and 2 summers; and died at home . . .	1
	18

LIVING.	First stage . . . 43	
	Second stage . . . 13	66
	Third stage . . . 10	
DEAD.	First stage . . . 5	
	Second stage . . . 11	34
	Third stage . . . 18	
		= 100

It is well known that, in chest disease, the general health must be invigorated as much as possible; and that injurious causes, exciting lung irritation, as cold, damp, and variable weather, are all especially hurtful, and carefully to be avoided. Now, in such a climate as that of Madeira, these injurious changes, and their consequent lung irritations, rarely, if ever, occur; and, when lung irritation does come on, it is much milder than at home; and there is this further advantage, that the tone of the system can be improved at the same time, by means not available in Great Britain during the winter and spring months. Cold or tepid bathing, sponging baths, moderate clothing, constant out of door exercise, riding, boating, sitting in the open air, or with open windows, are habitually used.

From the preceding observations and tables, we may consider it fully proved, that the opinion long held and expressed by the more experienced members of the medical profession, regarding the beneficial effects of a genial climate in chest disease, is the correct one; and that the statements promulgated against that opinion are not supported by facts, certainly not so far as relates to Madeira, and most probably not to Rome, Pau, or Egypt, with the proviso that properly selected—not dying—patients are sent to these localities. So far as regards Madeira, I could strengthen the details of its beneficial effects by relating individual cases; but that would unnecessarily lengthen this paper. Of one thing I am fully convinced, after many years' residence in Madeira; namely, that, in the early stages of phthisis, a person has in that place an infinitely better chance of having the disease arrested, than in England, or any other place that I am at present aware of; and that, in the latter stages, the disease is much delayed, the invalid enjoying all the comforts of life before finally sinking; and that a few cases occur, where the prolongation of life is very great. Many in Madeira live longer (say from three to four years) than the average duration of the whole three stages in Great Britain, which is limited to a period extending only from eighteen to twenty-four months. I have cases, where this retardation of disease has extended to ten, twelve, even twenty years; and one to twenty-five years. Many have lived on the island in perfect health.

brothers and sisters have, from a contrary cause, all died; or have originally come out as phthisical, and have lived free from all tubercular complaint.

August 1853.

TWO FATAL CASES OF SNAKE-BITE: WITH REMARKS.

By R. H. POWELL, M.D.Lond.

(Read before the Harveian Society of London.)

CASE I. The following particulars of a case of snake-bite were furnished by A. MacKean, Esq., late in medical charge of Mhairwara Local Battalion.

The accident occurred to a Sepoy, who was, I think (says the reporter), in the district on command; and when he was brought in, of course there was nothing to be done but to give spirits of ammonia from time to time. No particular symptoms supervened, if I except a disposition to drowsiness, and latterly acute inflammation of both conjunctivæ, for which leeches were applied to the under eyelids, and cooling purgatives administered. After the leeches had been applied, it became apparent that the leech-bites continued to bleed, and neither dossils of lint, applications of turpentine, nor of lunar caustic could command the partial bleeding from them. After the case had been altogether some three or four days in hospital, the man gradually fell into a lethargic state, from which he never could be roused. His leg was somewhat swollen on admission to hospital; and as no very urgent symptoms showed themselves, I was in hopes the case would have done well; but in this I was disappointed. It is impossible for me to say what kind of snake bit the man; nor can I positively assert it was a snake that bit him, but in all likelihood it was a case of snake-bite.

There are no further particulars to communicate.

(Signed)

N. COLLYER,

Assistant Surgeon, Mhairwara Local Battalion.

February 3rd, 1841.

The second case is reported by Mr. Davidson, surgeon, —th Light Infantry.

CASE II. Lieut. C. A., —th Light Cavalry, aged about thirty-three years, was bitten by a snake on the left instep, through a thin cotton stocking, on the night of the 11th June 1840, between nine and ten o'clock, when walking home from the regimental mess-house, and was brought to me about twenty minutes after the accident. Immediately on his being bitten, a ligature was tied tightly round the leg, and in a few minutes after a large dose of eau-de-luce (about 3 iiss), was given. On arriving at my house, he had no particular symptoms of the effect of the poison. He was anxious; the pulse was soft; he complained of soreness of his throat from the eau-de-luce. He had slight pain in the part which was bitten, the punctures were very distinct, and had a black appearance, and the foot was very slightly swollen. The part was cut out with a scalpel;* it consisted of the common integuments and cellular substance, to the extent of about nine lines in length, and eight in breadth, over the os navicular, and on the inner side of the extensor proprius pollicis pedis. It was allowed to bleed a little; and was then touched with lunar caustic, and a poultice was applied.

About two hours after the bitten part was cut out, he became restless, giddy, and sick, with a strong inclination to go to stool, and bleeding took place from the wound. On removing the poultice, the blood was found oozing out as from a sponge; and pressure having no effect in stopping it, though no vessel of any size was cut, or could be seen, ligatures were applied at every place where any distinct point could be discovered, and then a compress and bandage were applied. In spite of this, however, the bleeding continued, and the actual cautery was had recourse to, and a firm com-

press and bandage put on. Two doses of eau-de-luce, the first of 3j, and the second of forty minims, were given by me; and afterwards, from the pain in the throat, liquor ammoniæ in forty minim doses, and then compound spirit of ammonia in drachm doses, in camphor-mixture, repeated at longer or shorter intervals, from half an hour to an hour. As the pulse became weak and slow, and as no further symptoms of the effect of the poison continued, except the oozing of blood from the wound, early on the morning of the 12th, the ammonia was discontinued. As the bleeding from the wound, though much diminished after the application of the cautery, did not stop entirely, he, on the afternoon of the 12th, commenced taking subacetate of lead, in three grain doses, with half a grain of opium, every three hours, and this was continued regularly up to the morning of the 15th.

On the forenoon of the second day (the 13th), the foot and leg were swelled and painful to the touch, but cool. The part had a *blueish* appearance, and several *purple blotches* were observed on different parts of the body, particularly on the left arm; which spots afterwards became larger and of a *darker* colour. His bowels were acted on by pilul. colocynth. c. aloes grs. viij, with pilul. hydrarg. gr. ij, at bed time, followed by an enema the next day when necessary, and his strength was supported. Excepting a slight oozing of a light-coloured watery blood from the wound, he appeared to be getting on well till the afternoon of the 15th, the fourth day after the bite. His pulse then increased in strength and frequency; he complained of headache, sickness, and loss of appetite; and became much heated, with swelling, heat, and pain of the foot and leg, nearly up to the knee. Cold lotion was applied to the foot and leg, and eight grains of extract of colocynth, with the same quantity of calomel, were given; and the bowels not having been acted on in three hours, a solution of three drachms of Epsom salts, in two ounces of water, was given every two hours. After the third dose of this, as his bowels had not been acted on, a purgative enema was given, which operated freely. After his bowels were opened, he began to take a draught consisting of

Liquor. acetat. ammoniæ 3 ij.

Vini antimon. tartarizat. ʒ. xx.

Mist. camph. 3j.,

every second hour. Under the use of this the febrile symptoms subsided. During the night he was restless, and suffered a good deal from sickness, which was relieved by effervescing draughts.

Early on the morning of the 16th, he complained only of great weakness. Suddenly, in the forenoon, a little before twelve o'clock, a profuse damp perspiration broke out all over his body, followed immediately by convulsions. He was after this unable to speak. Slight convulsive twitchings of the extremities continued, and he gradually sank and died at a quarter past two P.M., of the 16th.*

EXAMINATION OF THE BODY three and a half hours after death. Externally nothing particular was observable, with the exception of the blotches on the different parts of the body, which had, from an *inky blue* colour, become *brownish*; and the discoloured state of the left leg, which had a *blueish* tinge extending up nearly to the knee. On examining the wound, a thin slough appeared to be separating, and there was a slight formation of matter round its edges, but no arterial branches could be traced into it. On cutting into the parts, there was slight extravasation of blood in the cellular substance around the wound.

Abdomen. The viscera were generally healthy; but the liver was rather large, particularly the right lobe, on the convex surface of which there was a mark of an old cicatrix, about two and a half inches long, and there was a red patch on its surface near to this place.

* A curved instrument, somewhat like a tenaculum, has been lately recommended for cauterising the punctures; following up their track, and effectually destroying the bitten tissue.

* It may be surmised that the treatment pursued subsequently to the exhibition of depressing astrigents proved too active for a system labouring under the sedative influence of a virulent poison. The latter part of the treatment was, however, judicious; and in such cases little room is left for critical remarks, from their all but universal fatality. N. H. P.

Thorax. The chest appeared rather small. There were chronic adhesions of both lungs, which were otherwise healthy. The pericardium was thin, and contained about two ounces of a pale-coloured fluid. The heart was very large, but not apparently changed in structure. The blood in the heart, as also in all the large vessels, both arteries and veins, of the thorax and abdomen, was quite fluid; and no coagulum of blood was found in any part of the body: its colour was also very light, and its consistence watery.

Head. The membranes and substance of the brain showed no diseased appearance. The lateral ventricles contained a small quantity of fluid, and the choroid plexus was of a rather pale colour. The cerebellum was soft. There was a considerable quantity of fluid in the spinal canal. The blood here, as in all other parts of the body, was of a light colour and very thin.

REMARKS upon this case by the reporter. The patient remained in my house. Mr. Griffiths, surgeon, 74th Regiment, N.I., saw him early on the morning of the 12th at my request, and continued to attend upon him with me till death occurred, and was present at the examination of the body. In this case the active effects of the poison were counteracted, to a certain extent, by the large dose of *eau de luce*; but the system was much affected by the virus, as was evident from the change produced upon the blood, the oozing of it from the wound, and the blotches on different parts of the body. Death was caused from the poison acting so severely upon a constitution which was much weakened by former illnesses. The snake was seen by Lieut. A., as well as by servants who were with him; and, though it was not killed, I have no doubt that the bite was inflicted by the *Karait*, a most venomous snake, which is common at this place. The effect of its bite is to produce a great change upon the blood, and to cause discharges of it to take place from the wounds inflicted by the animal—whether the parts be cut out or scarified or not,* as also from other parts of the body, as from the nose, or mouth.

Lieut. A. was of a spare habit of body, middle size, dark complexion, and of regular but rather sedentary habits. When coming out on board of ship, he had a fall on his back, which injured his spine so severely, that for some months after his arrival he was unable to do his duty. He did duty with the cavalry for a few months in the cold season of 1828, and was afterwards posted to it and joined in December 1829. During the time he was with the regiment, in 1830 and 1831, he was more or less an invalid, suffering from affections of the liver, and obstinate constipation, for which (besides other means) he was obliged daily to have recourse to purgatives and enemata. On the march of the regiment, in January and February 1832, he was attacked with fever, from which he suffered severely, and afterwards was so reduced and debilitated, that in this year he was sent on sick leave to England, but was a long time before he derived benefit from the change of climate, and for a considerable period he was obliged almost constantly to have recourse to the use of purgatives. In April 1837 he joined his corps on his return from England, and continued pretty well for some time afterwards. In 1838 and 1839, he was three times on the sick list, for considerable periods, for the treatment of primary and secondary symptoms, for which it was absolutely necessary to put him through protracted courses of mercury (it being difficult to bring his system under the influence of it); *sarsaparilla* and nitric acid being afterwards given. In December 1839 he got his right ankle hurt by falling over a tent-pin. Inflammation took place, for which leeches were applied; but the wounds ulcerated, and did not heal up for nearly a month. In April and May, he suffered from chronic disease of the liver; when blistering, counter-irritation, and mercurial alteratives and purgatives were given, with the effect of re-

moving the symptoms. With the exception of suffering from gonorrhoea, he continued pretty well after this up to the time of being bitten by the snake.

(Signed)

ALEX. DAVIDSON,
Surgeon Light Cavalry.

It may be doubted whether, in the above case, the lead and opium acted beneficially; as, while they moderated the discharge of blood from the wound, secretion and excretion were probably checked, and the eliminating process usually set up by the glandular apparatus was arrested in its salutary operation of freeing the blood and system from deleterious agents: the supervention of low congestive disorder being also proportionally facilitated.

GENERAL REMARKS UPON SNAKE-POISONING. With regard to the nature of the snake virus, it would appear to be related to those bodies, occasionally present in the blood as the result of or in connexion with defective excretion, and which, though differing greatly in degree of virulence from the former, exert an injurious influence not very dissimilar in kind.

The mode of operation of the snake virus on the blood, seems to consist of and originate in a catalytic influence, whereby the essential properties of the blood becoming altered, its constituent parts are broken up, and fall into lower and more simple organic combinations. These changes probably take place in those composite bodies formed by the mineral and azotised constituents of the blood conjointly. It would appear, from the foregoing and similar cases, that the fibrin and red globules are especially attacked and modified, as by other noxious agents; the plasticity of the blood being diminished and its fluidity increased, as in death from lightning, and from diseases in which those ingredients are affected. The cachectic state of the patient in the second case, related above, still further promoted the baneful operation of the snake-poison, in spite of the treatment occasionally found useful in this form of toxæmia. It is worthy of remark, however, that the antidote (ammonia) to those subtle and rapidly acting poisons, contains nitrogen; and that when promptly exhibited, it may be concluded to bear the early impression and attack of the snake venom rapidly gaining access to the circulation, and there neutralising its lethal activity, and thus preventing the decomposition above referred to.

It is obvious that, if the blood become chemically altered, congestion and other secondary disturbances of function may readily ensue, and make up the train of symptoms characterising such cases. There appears to be some analogy between the poisonous action of the snake secretion and that of belladonna; both producing tumefaction of the throat and of the eyelids, affection of the pupils; cerebral congestion, etc., supervening. Further, the excretion from the kidneys of uric acid and non-combustible salts is diminished by the latter agent, thereby permitting the accumulation in the blood of those injurious compounds previously mentioned. The alleged prophylactic power of belladonna in scarlatina, in which the presence of a zymotic agent may be assumed, may be derived from the incompatibility of two concurrent morbid operations in the economy, or to the fact of one catalytic agent, as it were, using up the pabulum required in the evolution of the other.

Moreover, Dr. Prout signalled the peculiar state of combination in which sulphur, iron, phosphorus, etc., are found in the organic principles of the blood. It may be in virtue of the poisonous ferment breaking up this combination that we are, in part at least, to attribute the formidable change of properties, and ultimate dissolution of the blood; either directly, by the formation of some less highly complex bodies; or indirectly, by the subtraction of the influence exerted by those elements in conserving the organised bases of the tissues from the operation of extra-organic chemical affinities.

Edward Street, Portman Square, August 1853.

* Why excise the bitten part in this case, if the absorption of the virus be not thereby arrested? It is probably a question involving the time and mode of performing the operation; speed and dexterity, with the subsequent use of additional means likely to still further promote the object in view, being the requisites for success. R. H. F.

BIBLIOGRAPHICAL NOTICES.

ON THE PATHOLOGY AND TREATMENT OF ACUTE RHEUMATISM, being the Lumleian Lectures delivered before the Royal College of Physicians in 1853. By JAMES ALDERSON, M.D., F.R.S. London: 1853.

THE attention which is now paid to acute rheumatism (judging from the number of books on the disease) is owing to the obscurity in which it is still involved, and the frequency of its occurrence. It is one of the most frequent of acute diseases now left; and, unlike the common inflammations, we suspect that very few practitioners feel any very great confidence in the best mode of its treatment. Dr. ALDERSON's object is to set forth a theory of the disease based on our more recent chemical knowledge, which will include and explain its causes, symptoms, and principles of treatment. Dr. Alderson is a believer in the value of thought. He considers that it is not enough to accumulate isolated facts and to leave them, but rather that we must endeavour, by reflection, to turn these materials to account by discovering causes. And no one will deny this; although in the present state of public opinion it requires some boldness to advance a new generalisation. To a certain extent this caution is a right one, as few minds are capable of true generalisation, though many may be able to reflect soundly on single cases. When, however, an earnest man shews that he has well thought over, and weighed, and endeavoured to balance and to estimate the evidence on a complicated subject, his labours demand attention; and no one will deny that our author has brought to his theme a well-stored mind, an acquaintance with the modern chemistry of the disease, and a disposition to investigate thoroughly its nature.

In acute rheumatism there is an excess of fibrin in the blood, and a deficiency of blood-corpuscles; so there is also in common inflammations. The peculiarity of rheumatism lies in its affecting the joints, and in its liability to metastasis. The chemistry of the morbid blood, therefore, proves rheumatism to be a species of the genus inflammation. Important questions to be solved are, How is this excess of fibrin caused? Why are the joints affected? How is it that metastasis occurs? A right theory of the disease should explain the phenomena; and the following is a slight sketch of Dr. Alderson's views. Respiration increases fibrin; and, on the contrary, fibrin diminishes in blood not brought into contact with oxygen. Thus, blood passed more frequently through the lungs becomes highly fibrinated by appropriating to itself more oxygen: blood which stagnates in vessels loses fibrin, for the fibrin is there used, and no fresh supply of oxygenated blood renews it. But in what way is the blood over-fibrinated in rheumatism? Cold (says Dr. A.) to the surface is the common cause of rheumatism, especially when the patient comes out of hot rooms, where he has been breathing a highly carbonised air. His carbonised blood eagerly seizes an over supply of oxygen, and an excess of fibrin is the consequence. This over-fibrinated blood circulates, and at the surface is chilled; the fibrin is not appropriated at the periphery to nutrition, but passes into the veins and to the heart, which it over stimulates, and thus the vicious circle is kept up with increasing effect. This over-fibrinated blood becomes obstructed in the fibrous textures of the joints owing to their peculiar structure, as their capillaries lie amongst unyielding fibrous tissue, and the natural relief of these obstructed capillaries is effusion into the textures. When this effusion happens, the obstructed vessels are relieved, and another joint is affected, which, in its turn, partially gets rid of the fibrin. This is the explanation, on a simple principle, of metastasis.

Such is Dr. Alderson's theory. The objection which immediately strikes us to the explanation of the over-fibrinated state of the blood is, that in a practical point too much is attributed to cold, and too little to the condition of the blood before cold was applied. This over-fibrinated state of blood is common to all inflammations; and, as a

general rule, what is called the predisposition to acute inflammation consists in a plethoric state of the system, usually produced by errors in the quantity and quality of food and drink for some time previously. Now, as fibrin is a constituent of chyle, the inference would be, from a consideration of the symptoms of the disease, together with its chemical history, that the excess of fibrin was owing to the digestive organs. But this could not be determined unless the condition of the blood, previously to an attack of inflammation, had been ascertained. So that the necessary data for an explanation of the over-fibrinated state of blood are not here given. Nor can we agree to Dr. Alderson's mechanical theory of obstructed capillaries as the cause of the joints being affected; for he himself admits that there is no such obstructing cause in synovial rheumatism, though there is in fibrous, and this admission seems to us fatal to his theory.

Why certain morbid states of blood affect certain tissues is a very curious and important question, and one still involved in great obscurity. Inoculate one man's blood with the syphilitic virus, and the poison will affect in succession the mucous membrane of his throat, his skin, his iris, his periosteum, and his bones. Another breathes the effluvia of a patient with typhoid fever in Paris, and Peyer's glands invariably ulcerate. Another inhales the poison of scarlatina, and his skin inflames in quite a peculiar way. Will any mere mechanical theory of obstruction of vessels from peculiarity of the structure of parts, throw any light on this large class of facts, which is much more extensive, when we also consider the effect of various medicines in acting (some-what like these morbid poisons) on different living tissues, both in health and in disease? Taking the whole facts into consideration, it seems most probable that the peculiarity in rheumatism should be sought rather in some morbid matter in the blood, than in the structure of the joints themselves. The old doctrine that there is a morbid matter in the blood in rheumatism, to explain its difference from common inflammation, may be the truer solution. Why that affects the joints, may be known when we have ascertained why the matter of inoculated syphilis affects the iris, or half a grain of calomel increases the secretion of bile, or acetate of potash acts upon the kidneys, or belladonna dilates the pupils. We fear that the consideration of this great class of facts shows that our knowledge is not yet sufficient for their explanation, but that we must be content to reserve our judgment.

Dr. Alderson's explanation of metastasis seems a very happy one. There can be no doubt that effusion is a natural relief of inflammation; and we see no reason why it may not be the case, that the so-called metastasis is simply the fact that, as one joint has done its part towards a partial relief of the overfibrinated blood, another goes through the same process in its turn.

No new plan of treatment is proposed; but the present modes are tested by the ascertained facts of the chemistry of rheumatic fever, and this is a legitimate and satisfactory proceeding.

Happily, the French plan of bleeding frequently, as a cure for rheumatic fever, is given up. Practice proved its inefficacy, and chemistry explains the reason; for bleeding increases the fibrin and decreases the blood-globules, and thus adds to the mischief. Its moderate employment at an early stage, in diminishing the quantity of the blood, and in thus diminishing the force of circulation, is its legitimate application. Local bleeding by leeches or cupping the joints is often very useful, when the pain, and heat, and local inflammation are very severe, and especially when they are limited to one joint. Now, chemistry shows that the blood taken from the surface capillaries contains a larger proportion of fibrin than that which circulates in the arteries and veins. It is richer in solid constituents than arterial or venous blood. The good effect of purgatives is, that they relieve the blood of its richer constituents, and of water (which is in excess in rheumatic blood), without depriving it of blood-corpuscles. Dr. Alderson approves of purgatives on purely chemical grounds; but objects to them as they in-

crease pain by the movements required. But as this may be much obviated by good nursing and the use of bed pans, we think the objection (which is commonly made by writers) unsafe, if the foul state of the tongue, and the light and offensive, or dark bilious stools, indicate their repeated employment.

As alkalis and acids are alike in their chemical action, from the salts of vegetable acids passing through the system as alkaline carbonates, the argument that they merely remedy effects, and not causes, is applicable to both. The alkaline treatment has been directed to the results of the disease—the acid perspiration, saliva, and urine—to the effects, not to the causes; but “the blood being essentially at all times alkaline, and being at the same time the medium through which all the characteristics of the disease, the inflammatory state, the fever, the affection of the joints, are induced, an attempt merely to saturate the system, as it is called, by alkalies, must be ineffectual as a curative measure”. As the nature of the acid of the skin and saliva has not ever been ascertained by chemists, chemistry alone can throw no light on the treatment of this symptom. Neither can chemistry explain why mercury checks the deposit of fibrin, or why acetate of potash acts on the kidneys.

It has been Dr. Alderson's object to discuss the old plans in the light of chemical science, and not to propose a new one: indeed, he has an antipathy to new plans. “I never feel more humbled than when I hear any regular practitioner proposing to try the efficacy of this or that plan. It ought to be for us not to try plans, but to know disease, and then use plans with confidence.” But supposing that this aversion had been universal, how could new remedies have been introduced. The use of tartarised antimony in acute pneumonia is eminently successful; so is the treatment of serous inflammations by calomel and opium. Both of these were not long ago new plans; and, if all had “felt humbled” when they were proposed, instead of adopting them, would mankind have been benefited? The fallacy is in the implied assumption that the knowledge of the nature of the disease gives us a knowledge of its cure. But the object of our art is to *cure* disease, not merely to know what it is; and when we merely know, or partly know the disease, and do not know its right treatment, the only justifiable way of discovering this is by judicious experiment—not letting the patient die while we are trying to reason out an appropriate treatment. This method may be carried too far, by incompetent persons; and we agree so far with Dr. Alderson as to believe that, whenever we can, the most judicious course is to treat disease according to the known principles of our art, applied to the particular case with our best judgment.

We must refer our readers to Dr. Alderson's book. Those who wish to know the chemical relations of rheumatic fever will find the facts here; and, whether they agree or not with his explanation, they will gain good by bringing their own minds into contact with one so thoughtful and full, and may be led to a closer study and to deeper views than they have yet had of the nature and relations of this important disease.

MEDICAL AND SURGICAL POCKET CASE-BOOK, designed for the Registration of Important Cases occurring in Private Practice. By JAMES PART, M.R.C.S. London: 1853.

THIS is a very well constructed Case-Book. We strongly recommend it to the busy practitioner who has not time to make copious notes of his cases, and is desirous of preserving some record of the more important of his daily observations of disease.

MANUAL OF MATERIA MEDICA AND THERAPEUTICS. By J. FORBES ROYLE, M.D., F.R.S. Second edition. 12mo., pp. 801. London: 1853.

IN this new edition of his admirable Manual, Dr. ROYLE has brought up his subject to the present time. In the

preface, he acknowledges the assistance which he has derived from Mr. F. W. Headland in making the formulæ and preparations correspond with the new editions of the Pharmacopœias of London and of Dublin, and for several new articles.

PERISCOPIC REVIEW.

ANATOMY AND PHYSIOLOGY.

SKELETONS ARTICULATED WITH CAOUTCHOUC.

In the *Glasgow Medical Journal* for July 1853, Dr. G. BUCHANAN describes a mode which he employs of articulating the skeleton by means of bands of India-rubber. A principal object is, to explain more readily the phenomena of dislocation. We quote, with slight abridgment, Dr. Buchanan's description of the apparatus.

“Reflecting on the various preparations of joints in common use, it occurred to me that a great improvement might be effected by the introduction of some elastic substance, the contraction of which would represent the action of the muscles. I had a skeleton prepared, with straps of vulcanized India-rubber, so disposed around the joints as to simulate the action of the muscles while the limb is at rest, and to imitate the direction in which they pull upon the bone when the position is altered. The result has been much more satisfactory than I anticipated. Most of the important dislocations can be imitated with the utmost nicety; and on artificial dislocation being produced, it is easy to notice the forces which act on the bone in its new position, and the direction in which the limb should be extended, in order to overcome these.

“In the shoulder joint, the muscles which act upon it may be resolved into three sets, and the direction of their forces may be represented by three bands of caoutchouc. One should be fixed to the upper surface of the clavicle near its scapular end, brought over the acromion process, stretched, and then attached to the anterior bicipital ridge of the humerus, near the surgical neck. This will represent the combined forces of the elevators, the upper fibres of the pectoralis major, the deltoid, the biceps, and the coraco-brachialis muscles, and will pull up the head of the bone towards the coracoid and acromion processes. A second piece of India-rubber should be attached to the front of the sternum, between the articulation of the first and second costal cartilages; it should be put on the stretch, and fastened to the bicipital groove of the humerus, a little way below the tuberosity. This will represent the action of the pectoralis major, and partly of the internal rotator muscles. Another band should be extended from the base of the scapula, just below the spine, to nearly the same point of the humerus as the last. This will act in the line of the depressors and external rotator muscles. The triceps has not much power over the motions of the joint, and its action is sufficiently represented by the weight of the limb. When these bands are properly stretched, as the arm hangs by the side, the bones of the joint will be found in their normal position. In the skeleton, as usually constructed, the bones are separated by the hinge or joining, nearly a quarter of an inch, so that the prominences are not seen in their proper position; but by the bones being kept in apposition, the exact shape of the joint is preserved, while the utmost freedom of motion is permitted. When the joint is dislocated, the bands give an excellent idea of the action of the muscles. The head of the bone being pushed back on the dorsum of the scapula, the posterior band holds it there, the upper one pulls it towards the spine, while the front one has little action. If the arm is held straight out from the body, and a slight downward stroke given to it, the ease with which dislocation into the axilla can take place is at once seen. When this dislocation has been produced, the upper band pulls the head against the neck of the scapula, and at the same time tends to raise or abduct the arm, while the other two pull it inwards against the ribs, and thus the elbow is kept projecting slightly from the side. A slight twist or shake will loosen or dislodge the bone, and enable the bands to act more forcibly upon it; so that the consecutive dislocation of its head upwards between the coracoid process and the second and third ribs, which not unfrequently happens if reduction has not been accomplished soon after the occurrence, can be seen taking place. In these, and similar instances, the bands kept on the stretch will indicate the muscles which help to produce or retain the abnormal position, and point out the direction in which force should be applied for the purpose of overcoming

their action. The necessity of waiting till the muscles have been well stretched, before attempting to push the bone into its proper place, is also well shewn.

"In order to represent the groups of muscles which move the hip-joint, the following bands of India-rubber should be attached:—One from the great trochanter, to a point on the dorsum of the ilium, nearly straight above it. This will represent the action of the glutei. Another from the body of the pubis to the lesser trochanter, to represent the action of the psoas and iliacus, and direct flexor muscles. Next, one from the ramus of the ischium, to a little below the femoral attachment of the last, indicating the adductor group. Lastly, the external rotators may be imitated by a strong band placed in the line of the pyriformis muscle. When these are well stretched with the weight of the limb, the bones are kept perfectly close, and the relation of the trochanter to the adjacent prominences of the innominate bone can be exactly ascertained, while the joint can be moved in any direction.

"Although the position of the head of the bone can be very well exhibited with a femur and pelvis, yet the most characteristic marks of the accident have to be imagined; while, on a skeleton of this kind, with one side normal and the other side dislocated, the altered position of the head and trochanter, length of the limb, and direction of the toe, are shewn with the most perfect accuracy.

"The muscles of the ginglymus articulation, as the elbow, knee, etc., are easily represented by four straps, one before, behind, and on each side, if the ligaments are strong."

CASE OF TRANSPOSITION OF THE VISCERA.

In the *Glasgow Medical Journal* for last July, Dr. ALLEN THOMSON relates a very interesting case, of which the following is an outline.

The subject was a man aged 48, who died in the City Poor-House of Glasgow. The malformation was not discovered until the body was being examined after death. It will be seen that there was not perfect transposition; the stomach, with some adjacent organs, retaining in part their position on the left side.

The heart pointed to the right side, and the arch of the aorta passed over the right side of the trachea and gullet. On opening the pericardium, the pulmonary ventricle and the systemic auricle were seen to the left of the heart, with the vena cava superior descending on the left side. The main pulmonary artery wound round the right side of the aorta, to pass below its arch. The arteria innominata, dividing into the left carotid and subclavian arteries, arose from the arch of the aorta, while the right carotid and right subclavian arteries arose separately, and in succession, from the arch. The remains of the ductus arteriosus joined the hollow of the arch towards the right, and was connected with the right branch of the pulmonary artery. The left vena innominata was short and vertical, and the right one long, and passing obliquely across the arteries rising from the arch of the aorta. The principal vena azygos was situated on the left of the bodies of the dorsal vertebrae, and passed over the root of the left lung. The pneumogastric nerve gave off its recurrent branch round the subclavian artery on the left side, and round the arch of the aorta on the right side. The relative position of the descending aorta to the vena azygos and thoracic duct, and to the vena cava inferior, was similarly modified; the latter vessel passed through an opening of the diaphragm between the middle and left divisions of its tendon. The right lung was divided into two lobes, and was hollowed out for the accommodation of the heart. The left was divided into three lobes. The intestines were found only partially covered by the omentum, which was thrown up to the left side. The liver was in the left hypochondriac and epigastric regions, the large (right) lobe towards the left. The gall-bladder, etc., were similarly inverted. The caecum coli was situated in the left iliac fossa, from which, after ascending a little way into the left lumbar region, it passed in front obliquely across the abdomen, deeply into the right hypochondriac region. A considerable part, therefore, of what might have formed the transverse part of the colon was sunk in the right hypochondrium. The descending colon was on the right side; the sigmoid flexure was attached in the right iliac fossa, and joined the rectum over the right brim of the pelvis. The greater part of the small intestines occupied the middle and right side of the abdomen, and the mesentery and great mesenteric artery and vein presented the same transposition. But the stomach, spleen, pancreas, duodenum, and a small part of the jejunum, had not undergone a change of place to the same extent. The stomach, somewhat elongated, was placed chiefly in the left hypochondriac region, below the

larger part of the liver and gall-bladder; but as the gullet passed through its usual place, the cardiac portion of the stomach was much drawn up, first below and next behind the smaller part of the liver, while the body of the organ lay lower down than the liver, in the left hypochondriac and lumbar regions, and the pyloric portion stretched forward and downwards towards the middle of the abdomen. Here, or a little to the left of the middle line, it joined the duodenum, which was raised from its usual deep situation, but otherwise nearly in its natural place, being directed towards the right, then curving downwards, and lastly, joining a portion of intestine which crossed the middle line towards the left, and making a sudden turn back to the right, passed behind the mesenteric vessels to terminate in the part of intestine corresponding to the commencement of the jejunum on the right side. This portion, directed towards the left, was not attached to the pancreas, and appeared to be a portion of the jejunum drawn out of its place. On this part of intestine a small rounded sacculated diverticulum existed, about an inch and a half in length and width. It was precisely in the situation in which we might expect it, supposing it to arise in connexion with the remains of the ductus vitello-intestinalis of foetal life. The spleen was attached to the great curvature of the stomach, and placed with it lower than usual under the liver in the left hypochondrium. The position of the pancreas departed only slightly from that of the natural organ, in consequence of the deviation of the duodenum. The kidneys were naturally placed, excepting that the left was somewhat the lower of the two. Complicated adhesions between the abdominal and visceral peritoneum in the vicinity of the duodenum prevented the state of the foramen of Winslow, and of the lesser cavity of the peritoneum, together with the attachments of the great omentum, from being ascertained with precision.

This is apparently not a very uncommon affection. In apparently the greater number of cases, the transposition affects all the viscera; in others, only one or more of them. The heart especially, and the liver, appear to be most constantly transposed. This state does not appear to exert any harmful influence on the functions. Its existence has been detected in persons at various ages during life. Isidore Geoff. St. Hilaire mentions his having seen living instances; and Dr. John Thomson detected this state of the heart in a medical student who suffered no inconvenience.

The earliest observation recorded is that by Riolan, in 1652, in the history of the dissection of a robber who had been broken on the wheel, in whom the malformation had not been detected during life. The first case which was ascertained during life, was that of a pensioned soldier of seventy-two years of age, observed and described by Morand, and reported on by Méry, in the *Memoirs of the Academy of Paris*, for 1666. The case is supposed to have suggested to Molière the transposition of the heart and liver, which he puts into the mouth of Sganarelle in his play of *Médecin malgré lui*, which was first published about the same time.

Dr. Thomson next enters into an examination of the probable causes, in the development of the ovum, giving rise to this malformation. He arrives at the conclusion, that "the partial or entire change of the non-symmetrical viscera is most immediately related to the change of position which occurs at the earliest period of formation of the heart and its main blood-vessels, the liver in connexion with one of those blood-vessels, and the alimentary canal."

PRACTICE OF MEDICINE AND PATHOLOGY.

VERATRIA IN ACUTE ARTICULAR RHEUMATISM.

According to the *Union Médicale* for April 2nd, M. M. TROUSSEAU and PIEDAGNEL, of Paris, have for some time employed veratria in the treatment of acute rheumatism. Its introduction appears to be due to M. Piedagnel, who states that, from the observation of numerous cases both in hospital and private practice, he finds that rheumatism is in this way generally cured in seven or eight days. He administers the veratria in the form of pills, each containing five milligrammes (about 1-13th of a grain). Of these, one is taken on the first day, two on the second, three on the third, etc., up to the sixth day; it is rarely necessary to give seven pills. When the general and local symptoms have abated, which generally takes place on the fourth, fifth, or sixth day, the dose is maintained for two or three days at the point at which it had arrived, and is then gradually decreased daily as the symptoms disappear; and when, after four, five, or six days of convalescence, the cure seems perfect, the medicine is discontinued.

If, during the administration of this medicine, colic, diarrhoea, or vomiting appear, indicating intolerance of the medicine on the part of the gastro-intestinal mucous membrane, no larger dose must be given than can be taken without producing this effect.

A great recommendation of this medicine, according to M. Trousseau, is the lowness of its price, especially as compared with that of the disulphate of quinine.

The following is an outline of some cases treated on this plan by M. Trousseau, in the Hôtel-Dieu.

CASE I. M., aged 17, had acute articular rheumatism, with endocarditis. All the joints of the upper and lower limbs were affected. Veratrin was administered; and the disease began to be subdued in three days. She left the hospital four weeks after admission; having remained there fifteen days after the disappearance of all symptoms, in order that the permanency of the cure might be established.

CASE II. B., aged 37, a day-labourer, had had rheumatism several times. He was admitted on March 12th, 1853, with acute articular rheumatism affecting most of the joints. The heart was unaffected. He took the veratrin in the manner described above, until March 22nd, when M. Trousseau discontinued it, in consequence of the presence of gastro-intestinal disturbance. The next day, the rheumatism, which had nearly left him, began to return in several of the joints. M. Trousseau then ordered four pills to be taken; after which he rapidly recovered.

Two other instances are related, of acute articular rheumatism; in these veratrin was employed with similarly favourable results.

EPIDEMIC (?) GOITRE.

At the meeting of the Société de Chirurgie de Paris, on March 10th, 1853, a communication was made from M. NIVET, of Clermont, relative to an epidemic of goitre, which he had observed among the students of the college in that place, and among the soldiers. He attributed the disease to the habit of frequently drinking very cold water when heated with exercise. The nature of the water, and the topographical conditions of the place, were not believed by him to be connected with the development of the goitre. The tumours were removed in a few weeks by the application of poultices, and friction with ointment of iodide of potassium.

M. DEGUISE, in reporting on this communication, considered that the author had not paid sufficient attention to the composition of the water and of the soil.

M. ROBERT doubted whether the disease observed was anything more than simple inflammatory engorgement of the thyroid gland. M. Deguise agreed in this opinion.

M. LARREY said that he had often seen soldiers attacked with acute engorgement of the thyroid gland. It was chiefly observed in men who had recently come from the country, and had been accustomed to have the neck bare. After wearing for a day the stiff military collars, they would in the evening, perhaps after a long march or some laborious service, throw off these, and thus expose the neck to the cold air. Hence there were two causes of the engorgement: the compression to which they had not been accustomed, and the suppression of perspiration from the sudden chill.

SPURIOUS PNEUMONIA PRODUCED BY A FOREIGN BODY IN THE AIR-PASSAGES.

Dr. THEILE, of Berne, relates, in the *Deutsche Klinik* for April 23rd, the case of a little girl, aged two years, who was admitted into the hospital at Berne, on February 11th, 1853. She had been suffering from cough for fourteen days. On examination, the respirations were from 70 to 80, and the pulse from 140 to 150 in a minute. The action of the intercostal muscles was very powerful on the right side, but scarcely perceptible on the left. On the right side, the stroke-sound was sonorous, and the respiration puerile. The left side was dull, and the respiratory murmur could not be heard there; but posteriorly there was some tubular breathing. There was violent dry cough, and much thirst. The bowels had been open four times in twenty-four hours. The urine deposited a copious sediment. The case was considered to be one of general pneumonia of the left lung; and was accordingly treated with calomel and frictions with oil of hyoscyamus and mercurial ointment. The child appeared to improve under this treatment until the 14th of February, when dyspnoea, frequency of the pulse, restlessness, hot skin, and retching, came on in the night; and the patient died on the 15th, at noon.

On examination of the body, the left pleura was found slightly

adherent. The whole of the left lung had a dirty grey colour, and presented no trace of the cellular structure. On section, a foetid, greyish, purulent fluid escaped, which was contained in small cavities from the size of a pea to that of a hazel nut, thickly spread through the whole lung. At the apex of the lung, and in the lower lobe, were two large cavities; in which there appeared to have been gangrenous destruction of the tissue. The proper pulmonary tissue could not be distinguished; in one or two places only could something like vessels be seen. The right lung was healthy. The other organs presented nothing worthy of remark.

In the left bronchus, five or six lines from the point of division of the trachea, was found a piece of charcoal, five lines long, three and a half lines broad, and one and a half thick. Where it lay, the mucous membrane of the bronchus was destroyed in the whole circumference; from this point to the trachea, and extending into this tube, there was inflammatory redness.

The supposed pneumonia was thus explained. It had arisen from total obstruction of the left lung, while the secretion of epithelium and mucus continued, and the secreted matters accumulated so as to simulate abscesses. The puriform fluid contained no pus-corpuscles.

Hasse (*Pathological Anatomy*, Sydenham Society's edition, p. 230) relates, from the *American Journal of Medical Science*, the case of a girl, aged 5 years, into whose trachea an iron nail fell. She died at the end of twelve months. On examination, the nail was found impacted in the fourth or fifth division of the right bronchus, and the lung contained several deposits of pus (?), communicating with the bronchial tubes.

CASE OF DIABETES FOLLOWING FRACTURE OF THE CRANIUM.

In the *Union Médicale* for April 23, Dr. E. SZOKALSKI relates the case of a man, aged 38, who fractured the parietal bones by a fall from a rock. Part of the left parietal was driven in at the sagittal suture, and the edge of the right parietal could be felt projecting. There was a sense of numbness and formication in the right side; motion was perfect in the leg and thigh, but not below; sensation was dull at the knee, and almost lost in the sole of the foot. Over the right deltoid muscle, sensibility was increased; though there was no redness nor swelling.

In a day or two, it was found that the patient was passing urine in large quantity. Dr. Szokalski found it to exceed the drink in amount; and, by the tests recommended by Mialhe and Bouchardat, he detected sugar in it. He attributed the diabetes to injury of the floor of the fourth ventricle, and treated it merely by withholding farinaceous food, by alkaline draughts, and by saline purgatives; expecting that the disease would disappear, in accordance with the observation of M. Bernard, that it soon ceases in animals in whom it has been induced by injury of the rachidian bulb.

In the fifth week there was marked improvement in every respect; the sugar in the urine had diminished. At the time of making his report, Dr. Szokalski found the urine normal in quantity, and free from sugar. The right foot had regained its power of motion; but the shoulder, though less painful, was still tender.

TANNATE OF QUININE IN THE NIGHT-SWEATS OF PHTHISIS.

In the *Union Médicale* for April 12th, M. DELIQUX describes several cases in which he has administered tannate of quinine with the effect of arresting night-sweats in cases of pulmonary consumption. He says that, though it is sometimes inferior to pure tannin, it is superior to disulphate of quinine; and that it combines the action of a tonic and antiperiodic. He gives it in powder, the quantity taken daily being from half a gramme to a gramme (seven and a half to fifteen grains), in three or four doses, taken at intervals during the afternoon or evening, so that the last may be administered three or four hours before sleep.

DRY CUPPING IN NERVOUS COLIC.

The *Journal de Médecine et de Chirurgie Pratiques* for April 1853, gives an account of the treatment followed by M. SANDRAS in cases of neuralgia of the abdominal viscera.

In certain cases, a patient is suddenly seized with symptoms resembling those of acute peritonitis; but the suddenness of the attack, and the absence of tenderness on pressure over the abdomen, point to the neuralgic nature of the affection. Sandras finds no means more efficacious than dry cupping, which instantly causing the cessation of the intolerable pain, he does not explain how this acts; but he has been successful in its employment.

COMPOUND ANODYNE APPLICATION IN SCIATIC NEURALGIA.

At the meeting of the Academy of Sciences in Paris, on April 16th, M. POGGIALE read a memoir on the treatment of sciatic neuralgia. He proposed the following formula.

R ^x Extract of belladonna . . .	5 parts.
Hydrochlorate of morphia . . .	0.4
Ointment	16.
Lard macerated with Stramonium leaves . . .	0.16
Essence of lavender	a few drops.

The ointment is applied by gentle and prolonged friction. The author related ten cases in which sciatica had been cured; all having been remarkable for the previous duration of the disease, the failure of the treatment previously employed, and the rapidity and persistence of recovery after the use of the application described above.

M. Poggiale believes that pain is a more important element in disease than is generally believed. In his opinion, it may be a powerful cause of disease, and may produce most severe symptoms. In many affections, pain is a predominant symptom, if indeed it does not constitute the disease; and on arresting it, the entire disease disappears. He also thought that it is too much the custom in the present day to prescribe simple formulae. A combination of substances of similar properties often produces better effects than the employment of each alone in succession.

GALIUM PALUSTRE (BEDSTRAW) AS AN ANTISPASMODIC.

The *Union Médicale* for April 30th, quotes from the *Revue Thérapeutique du Midi*, a letter from Dr. MIERGUES, junior, in which he speaks of galium palustre (bedstraw) as a powerful antispasmodic, and a remedy to be depended on in epilepsy.

The following is the manner in which it is prepared and administered. A quantity of the fresh plant is bruised in one-sixth of its weight of spirit. The expressed juice is then exposed to a temperature of 212; it is then filtered, and sufficient sugar is added to form a concentrated syrup, to which a fourth part of orange-flower water is added. The syrup is of an agreeable taste; and children take it with pleasure. The dose is a spoonful every hour when the attacks are imminent; and two or three morning and evening in other circumstances.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

ADMINISTRATION OF ETHER IN CAPSULES.

In the *Journal de Médecine et de Chirurgie Pratiques* for April 1853, M. CLERTAN, of Dijon, states that he has for some time been accustomed to give ether in capsules in nervous affections. After several years of observation, by himself and others, he concludes that ether, when introduced in a known dose, pure, and without loss, into the stomach, has an effect which was totally unknown until the preparation of the ether-pearls (*perles d'éther*). According to the old plan, the ether became partly volatilised before passing half way down the œsophagus; and what arrived in the stomach was dissolved in water, and in a state favourable to rapid and sudden volatilisation. M. Clertan has several times seen neuralgia, hemicrania, and gastralgia, arrested instantaneously by from one to three of these capsules; while ether draughts, and ether in syrup, had been largely given without any effect.

The editor of the *Union Médicale* for April 12th, in noticing M. Clertan's preparation, states that the ether capsules are already employed extensively by M. Trousseau, M. Pidoux, and other practitioners in Paris. The advantages of the capsules are:

1. The ether can be administered in a known dose—each capsule containing four or five drops.
2. The capsules are inodorous; so that ether can, without their knowledge, be given to persons to whom its smell is repulsive.
3. The capsules permit neither evaporation nor decomposition of the ether; they may be kept a year at least, or indefinitely, according to M. Clertan.
4. The ether arrives in the stomach without irritating the membrane of the mouth or pharynx, or producing cough; and it produces its sedative action by its rapid absorption.

DISEASES OF CHILDREN.

SACRAL CYSTS, COMPLICATED WITH SPINA BIFIDA, SUCCESSFULLY TREATED BY LIGATURE.

In the *Deutsche Klinik* for May 7th, 1853, Dr. SCHINDLER, of Greiffenberg, relates the following case.

Anna U., aged 2 years, was born with a tumour over the sacrum, of the size of a hen's egg. At the age of eighteen months she began to walk, and at two years old uttered only a few unintelligible words: in other respects she was healthy, and appeared tolerably well nourished and strong. Latterly, she had fallen several times, always backwards; which caused her much pain. The tumour, when examined, was not excessively distended; it presented more or less fluctuation at various parts; it was not very tender, and could not be reduced by pressure. On its surface, there was an appearance as of cicatrices; at its base, on the right side, it was covered with long light coloured hairs. It could not be felt what connexion the tumour had with the spine, or whether there was a defect in the bones; it was only felt that the tumour extended inwards, and was not confined to the subcutaneous tissue.

On June 7, 1852, Dr. Schindler introduced three pins; a clear serous fluid spouted out, and continued to ooze for some time; the tumour became flabby, but again filled in the course of the day. On June 12, puncture was repeated, with the same result. On June 15, the tumour was again distended; it was punctured, and a compress of plasters was applied. Subsequently, the tumour became more distended than before; Dr. Schindler therefore removed, by means of a small trocar, some spoonfuls of fluid, and injected a weak solution of iodine. This produced no inflammation nor diminution of the tumour.

After careful consideration, Dr. Schindler determined to apply a ligature. He was, he says, aware that ligature had been objected to, on the ground that, if the inner membrane of the swelling were formed by a prolongation of the dura mater, adhesive inflammation would not be likely to occur, and the spinal cavity would therefore remain exposed after the removal of the tumour; and, moreover, that union of the corresponding walls would be impossible, on account of the impediment afforded to the apposition of the surfaces of the arachnoid by the presence of nervous fibres; and, finally, that the removal of the tumour by ligature might be followed by the formation of false membranes, and that inflammation might become so intense as to remain localised, and to extend to the spinal cord and its membranes. To these objections, Dr. Schindler offers the following reply.

Pathological examination teaches that, in sacral cysts complicated with spina bifida, the fluid is, in by far the greatest number of cases, effused into the subarachnoid space; and that the arachnoid, with the dura mater, forms the lining of the sac, while the pia mater covers the spinal cord. In other cases, the fluid is contained in the so-called arachnoid space; and one layer of the arachnoid lines the dura mater in the sac, while another is applied to the pia mater in the spinal canal. In both cases, the inner lining of the sac is a serous membrane; and these are the most favourable conditions for the occurrence of adhesive inflammation. Those cases, also, in which cure has taken place spontaneously, or after puncture, show that adhesive inflammation can occur in the walls of the sac.

With regard to the presence of fibres from the lumbar or sacral nerves, Dr. Schindler observes that the ligature, if it be effectually applied, is preferable, as regards them, to the removal of the entire tumour by the knife. The objection, that the presence of the nerves will impede union, is of no force. The success of the ligature depends on the circumstance, that the sac does not contain the whole circumference of the spinal cord or the cauda equina; that the anterior lumbar or sacral nerves do not enter it; and that there is only partial effusion, and that this has no connexion, or very little, with the spinal canal. In the present case, it was plain that there was no part of the cauda equina present in the sac, as shewn by the absence of paralysis of the lower limbs, and by the absence of reaction after the employment of puncture and injection.

On June 20th, Dr. Schindler made a circular incision at the base of the sac, through its thick coverings, as far as the inner layer; he then applied a strong silken ligature, and tied it as tightly as possible. The child cried much, and passed feces and urine. The ligature was tightened daily, until, in a few days, this could be no longer effected. The tumour, nevertheless, continued distended, and of its natural colour. On the ninth day, there appeared a small bluish spot on the left side, and the tumour began to diminish; while the ligature was daily

drawn more towards the spinal canal. On the fifteenth day, the tumour was removed with scissors: the ligature was left. On the eighteenth day, Dr. Schindler drew the ligature from the cavity in which it lay: he had intended to apply another, but it became detached, and left a deep aperture, which, under the most simple treatment, became filled with granulations, and was cicatrised at the end of four weeks.

The child suffered much during the progress of the cure, though there were no nervous symptoms nor convulsions. When Dr. Schindler reported the case, she was perfectly well, cheerful, and strong, without any disturbance of health. It was not easy to ascertain by the touch whether there was any deficiency in the osseous structures at the part operated on.

The tumour had very thick walls, which were, however, of unequal thickness; and the cavity, which was unilocular, was moderately small. Two large nerves passed into the cavity; they were not connected with the lining membrane. They formed branches and anastomoses, and terminated in the integument at the apex of the tumour. M. Meckel, of Berlin, examined the tumour, and found it to be composed of two layers; the inner apparently composed of arachnoid, the outer corresponding to the dura mater. The very thick cellular tissue which covered these externally, he believed to be the product of inflammation. The structures which Dr. Schindler took for nerves passing into the tumour, he considered to be bands, arising also from inflammation; otherwise, if they were really nerves, it would be difficult to understand how puncture, injection, and ligature, should not have been followed by more important nervous symptoms: Dr. Schindler, however, adheres to this opinion, that the structures in question were nerves. M. Meckel believed that the tumour formerly communicated with the spinal canal, but that it had been shut off by closure of the opening in the bones.

Dr. Schindler recommends further trial of ligature of sacral cysts complicated with spina bifida. Until we are enabled to determine the internal structure of the tumour from its external characters, the following circumstances will give some aid in diagnosis and prognosis.

1. When there is paralysis of the lower limbs, bladder, and rectum, malformation, especially in the lower limbs, club-foot, etc., an operation will only be unsuccessful, and will accelerate death; for in these cases there is a very abnormal course of the nerves.

2. When the child has a large head, with widely open fontanelles, when pressure on the tumour produces retrogression of the fluid into the spinal canal, accompanied by convulsions and sopor, and when the distension of the tumour is affected by inspiration and expiration, nothing can be expected from ligature, and scarcely anything from puncture and compression, as the local disease is complicated with general hydrocephalus and hydrocephalus.

3. When pressure produces neither reduction of the tumour nor any symptoms, it may be concluded that the process of separation is already perfect, or that there is only a very small aperture of communication, or that at least there is only local hydrocephalus. The ligature is peculiarly indicated in these cases.

4. It is always most important to ascertain whether there are nervous fibres passing into the tumour; for it is only when none of the lumbar or sacral nerves, or only the posterior ones, enter into the tumour, that the ligature can be used without injury. If the anterior sacral nerves take their course through it, the result will be fatal. We are not yet able to ascertain this from the external form of the tumour; but the following circumstances may in some measure guide us.

If the fissure occurs in the lower lumbar vertebrae and the os sacrum, in most cases the whole circumference of the cord enters the sac, and from it spring the lumbar and the sacral nerves; or the cauda equina passes into the sac, and its nerves spread out in it. If the fissure is seated higher up, the cord is generally not displaced. Of eighteen cases collected by Von Barrensprung, in which he operated successfully, in six the disease was in the cervical and lumbar vertebrae; in four cases in the dorsal vertebrae, and in only two in the sacrum, although this is the most frequent seat of the disease.

If the external covering of the tumour is very thin and semi-transparent, consisting of a prolongation of the covering of the spinal cord, with an accidental epidermis, there is generally a greater amount of disorganisation, than when the external covering is formed of a thick areolar tissue, and the tumour appears to the touch as if it were made up of several cysts.

EDITOR'S LETTER BOX.

CHLOROFORM IN THE PRACTICE OF MIDWIFERY.

LETTER FROM EDWARD W. MURPHY, M.D., TO THE EDITOR.

SIR,—Chloroform in the practice of midwifery has again become a question for discussion; and, fortunately, its tone in your pages is more that of inquiry than controversy. There is evidently a very different spirit prevailing in the profession now, with regard to its use, than existed on its first introduction. It is no longer argued that to assuage the sorrows of childbirth is flying in the face of Providence; but rather that it is humane to relieve this anguish, provided it can be done with safety. "Every one," observes Dr. Ramsbotham, "who possessed the least spark of humanity, would receive with joy and gratitude so easy a method of abrogating or assuaging the pains of parturition, if it only can be proved that the practice is void of danger." (ASSOCIATION MED. JOURNAL, August 12, p. 714.)

I am encouraged, therefore, to trespass on your attention, and, if possible, to convince Dr. Ramsbotham, and those who think with him, that chloroform may be given, not only with safety, but with positive advantage, in the progress of severe labours, and may be used, with very few exceptions, in all cases where the intensity of the patient's sufferings, is evidently more than she can endure.

It would be impossible, however, to produce conviction, if in our discussion the *post hoc, ergo propter hoc* sophism be admitted. If every accident that may occur after delivery, and every bad consequence that may follow labour, is to be charged against chloroform, and chloroform alone, because this agent had been employed, it would be a waste of time to argue the question.

Mr. Bloxham observes, in your last number, "that some advance may be made towards settling the question as to the use of anæsthetics in labour, by exposing the errors in reasoning of the authorities who have discussed this subject." In this I quite agree with him; and if in these discussions the opponents of chloroform in the practice of midwifery have cause to complain of a *non sequitur*, with how much more reason has Dr. Simpson and its advocates the right to object to the bold manner in which this sophism is used?

There is no accident that could occur after delivery, that has not been attributed to chloroform. Hemorrhage, puerperal convulsions, puerperal mania, puerperal fever, have all had chloroform assigned as their cause; as if such effects of labour had never been observed until its introduction. It is hardly necessary to dwell upon the inconclusiveness of such a mode of reasoning, although it is surprising the constancy with which it is adopted; but, in the present instance, I am induced to allude to it more particularly, because in two cases, where chloroform had been given, sudden death occurred some time after delivery, and in one of them at least, if not in both, death has been assigned to the agent employed.

One case had been communicated to Dr. Ramsbotham by his friend Mr. S., and is reported in his *Obstetric Medicine*. Having given a brief history of the case, Dr. R. proceeds: "Parturition came on about noon; the chloroform was given at half-past seven P.M., when the os uteri had acquired the diameter of an orange, and the pains had become frequent and strong. The effects were at first delightful and tranquillising. After refreshing sleep, she rose and bore some moderately strong pains for an hour, without a return to chloroform. It was then resumed, and repeated in frequent half-drachm or drachm doses, but (except once) only when she entreated to have the delightful chloroform, from about ten P.M. till a quarter before twelve o'clock, soon after which the child was born. She instantly expressed much gratitude, and expatiated on the relief afforded her, though even then she felt wrong with the severity of her labour. The uterus contracted well, and the patient appeared comfortable."

"At the end of an hour and a half, distressing dyspnoea came on, attended with excessive lividity of the face, and all the signs of extensive engorgement of the lungs and head. Her respiration became more natural under the means employed, and in three hours and a half she lay down to rest; but in half an hour she suddenly arose, with a return of most distressing dyspnoea, that was soon followed by convulsions, and almost immediate death. No post mortem examination was made." (Ramsbotham's *Obstetric Med. and Surg.* p. 169, third edition.)

In this case, it is evident that the quantity of chloroform given was very small, not sufficient to remove, completely,

She was once only put to sleep, awoke refreshed and was afterwards given chloroform only as she asked for it. When the child was born, she was sufficiently conscious to "express much gratitude, and to expatiate on the relief afforded her."

A very similar case to this occurred in my own practice, which, as I have already alluded to it in my published lectures, I shall quote from that work. "I was summoned to attend a lady in her first confinement, who had been taken in labour the previous night. I saw her about eight A.M.; the dilatation of the os uteri was advancing favourably, and was completed at ten A.M. As soon as the head entered the pelvis, and the pains became very severe, I administered chloroform by the mouth: the severity of the pains were greatly mitigated; she remained quite conscious throughout, and was delivered in two hours. When the placenta was expelled, she fell asleep. On awaking, two hours afterwards, she was seized with slight cough, and some difficulty of breathing; the means used gave no relief, and in the evening dyspnoea had so much increased, that she was cupped to ten ounces. This gave sufficient relief to cause sleep for about two hours; but when she awoke, the dyspnoea returned with still greater distress, and continued to increase during the night. On the following morning she became asphyxiated, and died about two o'clock P.M."

A post mortem examination was made, the kidneys were found extensively diseased; the blood, which coagulated loosely, was carefully analyzed, but no trace of chloroform could be detected. The lungs were highly congested. (*Lectures on Midwifery*, p. 474.)

These two cases resemble each other in their leading characters; both had inhaled sufficient chloroform to relieve pain, but not to remove consciousness. Each was perfectly tranquil for more than an hour after delivery, when dyspnoea commenced, terminating in fatal asphyxia, in one case in four hours, in the other in twenty-four hours, from the first difficulty of breathing. Both inhaled chloroform, both died asphyxiated; therefore chloroform was the cause of death.

Let us examine this conclusion. The action of chloroform and its manner of causing death is now tolerably well understood.

In surgical practice, several thousand patients have inhaled chloroform. Suspension of animation has been caused by it, and death has followed its use; but I cannot find the report of a single case in which the patient, who inhaled chloroform, without one unfavourable symptom, was attacked two hours afterwards with dyspnoea, still later became asphyxiated and died. When chloroform is given for surgical operations the patient is rendered unconscious, immovable; the full dose—the dangerous dose—is given. If then this agent could produce such effects in minor doses, which do not influence the brain, *a fortiori* it should do so when the larger dose is given, yet I cannot find a case of the kind in the whole range of surgical practice. Chloroform can act on the constitution only through two channels; through the nervous system or the blood. Either or both may be means of manifesting its action, but I know of none other. The action of chloroform on the nervous system is to paralyze its force. It diminishes sensation, lessens the motive power, removes the irritability of the respiratory nerves, and the consciousness of the patient; but I do not perceive how it can cause convulsive dyspnoea where that irritability, the *besoin de respirer*, is in excess. If we admit, however, that it might do so, but nevertheless find that no such result attended its inhalation, "when the effect was delightful and tranquillising"; "when the patient rose after a refreshing sleep, bore some moderately strong pains without a return to chloroform"; and (chloroform being resumed until the birth of the child) when the patient "expressed much gratitude"—"expatiated on the relief afforded her". When "the uterus contracted well, and the patient appeared comfortable", when all this happened, it is clear that chloroform did not cause any unfavourable effect on the nervous system. In each case the dangerous symptoms presented themselves more than an hour after chloroform had been inhaled. At a time when the vapour was dissipated, or, if any remained, its force greatly weakened and less likely to cause such effects. It would, therefore, be rather a bold assumption to say that in either of these cases chloroform caused death by its influence on the nervous system.

There remains, however, another mode in which chloroform may influence, or at least is supposed to influence, the constitution. It may alter the blood. It is said that chloroform incorporates with the blood, renders it impure, and therefore might produce such symptoms as have been described some time even after its inhalation. Is this true? Two gentlemen who have given the most attention to the effects of chloroform on life—

Dr. Snow and Mr. Nunneley—both agree in this—that chloroform does not incorporate with the blood or in the least alter its properties. This proposition, supported by a careful experimental inquiry, has also the support of experience; because, if chloroform influenced the blood in this way, its effects must be observed in surgical operations. The greater risk of secondary hæmorrhage, the unhealthy healing of a wound, and other obvious effects of impure blood, would become manifest. If dyspnoea and asphyxia be one of these, then such symptoms should follow surgical operations just as readily as labour. The evidence, however, of surgical practice is quite the reverse; the danger—the only danger which the surgeon dreads is sudden death during the operation; but if he escapes this he has no fears that his patient will afterwards die asphyxiated or from secondary hæmorrhage, and from gangrene of the wound. Thus this assumed effect of chloroform on the blood is only confined to midwifery practice, and may be viewed as another of many assumptions respecting it which is well calculated to deceive those who have not examined, or, perhaps, who cannot, from their numerous avocations, find time to examine carefully its effects.

I shall not attempt any explanation of the cause of death in either of those cases. Unaccountable sudden deaths after delivery is nothing new. Dr. Cormack has ably pointed out some of the causes of death in these cases (*London Journal of Medicine* for 1850, p. 928); and there may be others; but, inasmuch as they are not as yet perfectly understood, it would be beside the question to enter upon such an inquiry. I shall only content myself with asserting that chloroform had nothing whatever to say to the death of either of these patients, nor can I admit, that because "I never saw such symptoms supervene after labour as those which appeared in that case, and as I do not recollect of any such on record, we may fairly refer them to chloroform". If we were to adopt such an argument, chloroform would become the most convenient *locus ignorantie* in the world.

A medical friend of mine attended a lady successfully through her confinement which was most favourable, she was apparently quite healthy, bore her pains cheerfully, was delivered in a few hours, and continued well for several hours when she was seized with convulsions and died. There was no cause to explain so unexpected an attack. My friend was fortunate in not having given her chloroform; because, had it been administered, it would have supplied the deficiency. The case would have been quoted as one in which chloroform clearly caused convulsions.

I feel it my duty to point out this erroneous mode of discussing a very important question, because it is as plausible as it is deceitful, and is well calculated to intimidate the anxious inquirer. It prevents him availing himself of a means of relieving the agonies of his patient, which he finds, or will soon find, his better informed rival is adopting with perfect safety and success, and completely confuses any just or rational inquiry into the effects of chloroform on the constitution.

Every day's experience convinces me of the great value of chloroform in the management of labours, so much so, that I have not the slightest doubt of its general adoption by the profession. Any inquiry into its administration must be based on such an assumption, if it is to answer any useful purpose. It seems to me much more likely that chloroform may be abused than disused, and more danger that it may be given recklessly without any knowledge of its properties than that it would cease to be administered in the practice of midwifery. The questions, therefore, of most importance in connexion with it concern the mode of its administration, the varieties observed in its effects on different constitutions, when it may be safely given, when it must be withdrawn. With such an object, I shall be most willing, at some future opportunity, to give a further account of my experience of it, so as to aid in the object so well pointed out by Dr. Ramsbotham, and assist in collecting "a mass of most valuable evidence which might thus be accumulated, from which it would be easy to lay down some fixed principles for our guidance". I trust also that it may have the effect of dispelling the uncertainty and doubt that as yet cloud our judgment, and proportionably embarrass our proceedings. I am, etc.,

EDWARD W. MURPHY, M.D.

12, Henrietta Street, Cavendish Square, London.

THE CLUB SYSTEM.

LETTER TO THE EDITOR.

SIR,—In the JOURNAL for July 22nd, I was much gratified to read, that, at the meeting of the South Eastern Branch, the subject of sick and benefit clubs and their abuses had been discussed. That their abuses are great and increasing, no member of our profession who has had anything to do with them

can deny; but that the remedy for these abuses is in our own hands, I am perfectly sure, provided only there be unanimity of action. The men of Canterbury have set a good example, which ought at once to be followed throughout the kingdom.

I happen to have been largely connected professionally with benefit clubs for the last dozen years, and at present am surgeon to ten such societies. I am sure none can have greater pleasure than myself in attending, on club terms, the labourer and meehanic, whose scanty earnings cannot possibly meet even a very moderate medical account; but when I find tradesmen, farmers, publicans, etc., insinuating themselves into these clubs, seeking for medical attendance on the same terms—which are in reality partly charitable—as the labourer, and drawing their “sick pay” from the same fund, I am truly disgusted, and give my time and labour with very different feelings to what I do in the former case. Not that I have many such club members; but a few there are in almost every club, who, having entered at the commencement, and being old members, cannot well be got rid of, unless, indeed, their cases can now be met by the plan initiated by the Canterbury surgeons in the Lodge of the Manchester Order of Odd Fellows; that is, the payment of the medical man's ordinary account for attendance on such members from an “Incidental Expenses Fund”.

Perhaps the following will show how far a medical man has it in his power, even single handed, to remedy the evil. Some years ago, an Odd Fellows Society, to which I am surgeon, became apparently flourishing, and, one following another's example, a rush was made by a number of substantial farmers to become members, under the candid confession, that they “did not want sick pay, but only the doctor”. I at once resigned. The old members, who were almost to a man labourers, saw at once the reasonableness of the objections I made. The farmers were refused as ordinary members, and I was re-instated. Of course, the step I had taken gave offence at first, but in the long run I did not lose a patient; and I have since received many a substantial fee from those who, but for the stand I made, would have been club patients on the same footing as their labourers.

Some of the worst cases of imposition upon medical men, however, are with the publicans, who become members of the clubs held at their houses, in their characters of “host” and “hostess”. It is needless to remark, that such persons are generally well able to pay a medical man. By all means, if persons above the class of labouring poor wish to insure themselves against the chances of illness, let them do so, but let it be by some such means as that adopted in the Odd Fellows Lodge at Canterbury; that is, by a general fund applicable to the discharge of a medical man's just and regular charges. I may remark in passing, that this is a mode of assurance against the misfortunes entailed by illness, which it surprises me has not hitherto been adopted. It is one, also, which without in the least trenching upon the privileges of the medical profession, might be found of the greatest service to persons of limited income.

To return to our subject. I fear that all who know our profession, know also that the great difficulty in resisting the encroachments and impositions made and practised upon us, is the want of unanimity of action and distrust one of another, the latter too often well founded; for, how frequently is a post resigned by one man from honourable motives, accepted, nay, canvassed for, by another.

This part of the subject might well be taken up by the Association, as far at least as its own members are concerned, and some plan of action decided upon calculated to stem this undercurrent of an abuse which is inflicting incalculable mischief upon us. The importance apparently attached to these benefit club appointments by medical men, and the canvassing and intriguing among the members which is too often practised, must, to some extent, create the idea that the appointments are of real profit; and perhaps this fact may have in some slight degree contributed to give those who ought to be above such relief, the idea that they were rather conferring a benefit than taking an advantage. Much depends upon the influence which the surgeon himself obtains among the members of his clubs. If he makes himself valued, particularly by the poorer members, and if they feel that his skill, kindness, and attention, are given to them in the same manner as to the rich, they will not easily part with him; he has thus, justly, much power, and may use it; but if, as too often happens, club members are systematically neglected, it need not be matter of surprise if the surgeon is but lightly valued, and if the members, feeling that his services may be easily replaced, successfully resist his attempts at self defence, and at club reformation.

In considering the subject of sick clubs, that of the more pretentious friendly societies, and of some forms of dispensary, founded and fostered by the higher classes, and frequently by the clergy, ought not to be lost sight of. Many of these societies include both adult members and children, far above the class of either labourer or mechanic, while the medical remuneration is often lower than even that of the common club. This is so much the worse, as the founders and conductors of such societies are not ignorant of what ought to be proper professional remuneration, only they are tempted for the sake of showing a flourishing balance sheet, to commit the injustice, and medical men are foolish enough to submit.

The power, present and increasing, which our Association possesses ought to enable it to take up this important subject with success, and while its members might resist the evil as far as they could personally, there can be little doubt that their moral influence among their brethren of the profession who are not members of the Association would greatly assist the work. I would suggest whether it might not be expedient to issue, to the members of the Association, circulars containing a series of queries relative to the working of the sick clubs, of all denominations, friendly societies, dispensaries, etc., within their respective districts, as a first step towards the correction of an abuse which is becoming a real oppression to a large section of our profession.

I am, etc., S. T.

August 5th, 1853.

ANEURISM OF THE AORTA OPENING INTO THE PULMONARY ARTERY.

LETTER FROM J. THURNAM, M.D., TO THE EDITOR.

SIR,—I beg to refer Dr. Herapath and such of your readers as may be more particularly interested in the unusual circumstance of aneurism of the aorta proving fatal by rupture into the pulmonary artery, to a paper in the 23rd volume of the *Medico-Chirurgical Transactions*, in which all the known cases of spontaneous varicose aneurism are collected and reviewed. Two or three additional cases and several preparations, in which the aneurism had become ruptured into the pulmonary artery, are there described.

I am, etc.,
JOHN THURNAM.

Devizes, August 25th, 1853.

NEWS AND TOPICS OF THE DAY.

PROSTITUTION IN ALGIERS SINCE ITS CONQUEST BY THE FRENCH. From the *Union Médicale* of May 21st, we learn that Dr. E. A. Duchesne has published a work on the above subject. Various works have appeared on prostitution in several of the French towns and cities:—in Paris, by M. Parent-Duchatelet; in Lyons, by Dr. Potton; in Nantes, by the Medical Society of that place; etc. M. Duchesne has effected this for the town of Algiers.

From credible documents, it appears that prostitution existed in Algiers in the sixteenth century, though it was then neither tolerated nor subjected to regulations. At a later period, the toleration and regulations were established, which the French found in 1830; at which period, there were three thousand prostitutes. How they were regulated is not precisely known; but they were divided into classes, and confined to private houses, which they could not leave without permission of the *mezouar*, a kind of lieutenant of police.

M. Duchesne states prostitution and sodomy to be both common in Algiers: the latter vice being prevalent not only among the natives, but even among Europeans. Boys of ten or twelve years old are met with in the most public places, making the most disgusting proposals. Sodomy is not regulated; and even if it were, this would be tolerating the vice. What is required, is its total annihilation, by means of a rigorous surveillance and severe penalties.

The number of prostitutes in Algiers does not seem to exceed 600, in a population of about 50,000. Most of them are Arab or Moorish females. The native prostitutes are mostly the children of poor families, who thus gain a living. In Algiers, as in Europe, the population of the towns furnishes more food for debauchery than that of the country; the Moorish prostitutes inhabiting the towns are always the most numerous. No information as to age can as yet be obtained.

In 1830, a dispensary and infirmary was established in

Algiers, containing eighty beds. It is under the care of one medical man. The public females attend the dispensary every morning at seven o'clock. In 1842, the number of females thus attended was 5186, of whom 446, or 8 per cent., were diseased. From a table of the proceedings of the dispensary from 1831 to 1851, it appears that the duration of treatment was from fourteen to thirty-nine days; from which it may be inferred that only primary and local symptoms are treated. In the tables given, the columns of patients affected with primary symptoms amount to 55, 135, 80, and 78; while those of constitutional symptoms amount only to 6 and 8.

There are few or no public females in the Arab tribes; hence there is little syphilis. The Arabs believe that syphilis may be transmitted to a negro female; the individual thus transmitting it becoming free from the disease. Before 1830, the black female slaves had to submit to this; the result of which was to double the number of persons infected.

M. Duchesne concludes with a proposal for establishing in Algiers a workhouse, a home of refuge, and a council of health; as well as a system of regulation of public prostitution.

STATISTICS OF PUBLIC CHARITIES IN PARIS. The report of the administration of public charitable assistance in Paris during 1852, has lately been published. In that year, 90,486 patients were admitted into the hospitals; and 12,117 aged and insane persons were received into the almshouses and asylums; making altogether 102,603. The number in 1851 was 98,754; hence the increase has been 3,849. On January 1st, 1853, the number of children abandoned by their parents was 14,111, of whom 282 were in the public institutions, and 13,829 in the country. The ordinary receipts amounted to 12,767,290 francs (£531,870:8:4); the expenses to 12,238,703 francs (£509,945:19:2).

Certain alterations and improvements have been introduced into these institutions. By a government regulation of March 5, 1852, all pregnant women presenting themselves at the hospitals are interrogated as to their name and place of abode, and a copy of their statement is immediately forwarded to the central bureau, which, in the course of twenty-four hours, ascertains whether it be true or false. If the statement is found to be false, or if the woman has not resided in the department of the Seine during a year, she is dismissed, unless labour is close approaching, or the woman is ill. When delivery has taken place, the mother is obliged to suckle her infant, and to take it with her when she leaves the establishment, unless unavoidably prevented. A supply of child's linen is supplied to those who are destitute of it; and a wet nurse is provided when the mother is unable to suckle her infant. To those who suckle their children, aid in money is granted, besides the assistance which they may obtain from the maternity charities, or other charitable institutions.

The effect of these measures has been, not only to reduce the number of admissions into the obstetric wards, but, what is more important, to diminish from 33 to 4 per cent. the number of deserted children at the Maternité, and to diminish it to 19 per cent. in other hospitals.

THE CLUB SYSTEM IN FRANCE. The editorial committee of the *Union Médicale* is sometimes consulted in medico-ethical matters; and in that journal for April 12, we find a letter addressed to it by Dr. DUFAY, on the subject of medical attendance on clubs (*sociétés de secours mutuels*). The objects of these are the same as those of similar institutions in England. The members are of two classes: *honorary*, who contribute to the funds, and are supposed not to receive gratuitous relief; and *participating* members. This distinction, however, as in England, is often not attended to; and Dr. Dufay writes:

"But if we have some right to pride ourselves on our acts of charity, is it not our duty to take care that they are properly recompensed by those who can do so? And would it not be at once a dereliction of our duty to our brethren, and a lowering of professional dignity, to accept a position which would oblige a practitioner to visit the *rich* as well as the *poor* members of a club, thus depriving his brethren of a practice from which they could obtain some reward for their trouble, and throwing away his own services, as if he doubted whether they were worth anything? If it is no idle scruple which dictates these lines, we must conclude that we ought not to perform the duties of medical officers to clubs on the ordinary conditions—almost gratuitously, until the subscribers who are known to be able to pay for attendance are ranged in a *honorary* or *non-participating* class."

In reply to this letter, the committee of the *Union Médicale* first call attention to the importance of union among the members of the medical profession. They have seen numerous

examples shewing that selfishness and antagonism do good to no one, and injure every one. In some districts, where a club has offered a thousand francs a-year to a medical man, another practitioner has proposed to attend the patients for five hundred francs, another for two hundred and fifty, a fourth for nothing. The committee advise that, when a club is formed, the medical men of the district should agree on the terms on which they would hold office. The practice of some clubs, which only pay fifty centimes for a visit, and some which pay for only eight visits, whatever may be the duration of the disease, is declared to be insulting and humiliating to the medical profession. Annual salaries are believed by the committee to be preferable to payment for each visit. It is well known that, both in Paris and in the country, a large number of persons, beyond the reach of want, enter themselves on the list of participating members of the clubs. In these cases the committee states it to be the right, the imperative duty of practitioners, to point out the abuses. And it will be, they assert, much more effectual, dignified, and convenient, that an appeal on this subject should come from an assembled body of practitioners, than from only one.

The committee suggest the following as the *beau idéal* of the constitution of a club, with regard to medical aid. The medical aid should be organised by the practitioners themselves, combined in associations, according to the locality in which they reside; the patient should be at liberty to choose his own medical attendant; the medical man to be paid should be chosen by the practitioners from among themselves for a limited time, so that all might participate in the advantages. This, however, is only given as a suggestion.

SURGEONS' CHARGES AND SICK CLUBS. In the Dorington County Court, Mr. Hall, surgeon, sued a party named Revell for £14:16:6, a charge for medicine supplied and attendance upon his son, who belonged to a juvenile sick club, the members of which pay 1s. 6d. until they are twenty-two, when they join the senior club, paying 2s. Of these clubs, Mr. Hall is the surgeon. As defendant's son attained twenty-two, and as he had not entered the senior club, his subscription of 1s. 6d. was returned last Lady-day, he not being a member. Hence the present action. Mr. Rouse, surgeon, proved that the bill was very moderate. The judge remarked, that he found that the bill charged 12s. for boluses and other medicines supplied in one day, which he would not allow, when medicine was so cheap. Professional men ought to be well paid for their services, but not for drenching their patients with physic. His Honour ultimately decreed the defendant to pay £2:15:0.

IMPORTANT ADJUDICATION. Dr. Rayner, an English physician residing at Paris, recently brought an action before the Civil Tribunal of Senlis, against M. Alexandre Aumont, of Chantilly, the owner of *Hervine* (who ran second for the Goodwood Cup) and other horses, well known on the French turf, to recover from him 10,000 francs, for having cured him of a serious malady. It appeared from the statement of the plaintiff's advocate (M. Chaix d'Est Ange), that in 1851, M. Aumont suffered dreadfully from nervous attacks and another malady. After employing different physicians without obtaining much relief, he, when almost in a dying state, applied to the plaintiff, who consented to treat him on condition that he would scrupulously follow his advice, and not employ any other physician. On the plaintiff's second visit, M. Aumont asked how much he would have to pay, and Dr. Rayner proposed that he should give him 10,000 francs when he should be entirely cured, but not a single sou in the event of a cure not being effected. M. Aumont consented, and it was agreed that, should his horses not win certain races at Paris and Chantilly, the amount, instead of being paid at once, should be paid by instalments. Dr. Rayner having acceded to these terms, the treatment commenced, and in a short time M. Aumont was a good deal better, and before long was so perfectly cured of his nervous malady that he was enabled to go out shooting and ride about as usual on horseback. Dr. Rayner was then about to commence a treatment for the other malady, but he found that M. Aumont had, contrary to their express stipulations, consulted Dr. Nelaton. He thereupon ceased his visits, and M. Aumont refused to pay him the 10,000 francs. M. Fontaine, advocate for M. Aumont, mentioned that the agreement on which Dr. Rayner relied was contrary to the rules of the medical profession; he had not cured him, and therefore maintained that the 10,000 francs were not due, though he was ready to pay him anything reasonable for his attendance. The tribunal, taking all the circumstances into consideration, condemned M. Aumont to pay Dr. Rayner 4000 francs with interest, and the costs. Dr. Rayner's

only motive (says *Galigiani*) in bringing this action, was to try the question of right, after attacks had been made upon his character. His object was not money, for he could have had more to keep the case out of court; and in proof of this, the plaintiff has declined to receive the 4000 francs damages awarded by the court, having disposed of that sum as follows:—1000 francs to the poor of Senlis; 1500 francs to the Association of Physicians of the department of the Seine, for the foundation of a *Casse de Prévoyance*; and 1500 francs to the Medical Benevolent College at Epsom.

NORFOLK COUNTY HOSPITAL FOR THE INSANE. We are glad to find, from the subjoined circular, that this institution is to be made available to members of the medical profession, for the study of mental diseases:—

"SIR,—I have the pleasure to inform you that the visiting justices have agreed to a proposition which I brought before them at their last meeting, viz., 'to throw open the wards of this hospital, on fixed days *specially*, to the members of the medical profession, under certain regulations'. I have therefore fixed Wednesday and Saturday, from eleven until two o'clock, for this purpose, when I shall be happy to give you every opportunity in my power of becoming acquainted with the internal arrangements and treatment of patients in this institution.

"I am, Sir, your obedient servant,

"R. F. FOOTE, M.D., *Resident Physician*.

"August 20th, 1853."

ROTHERHAM DISPENSARY. On Wednesday week, a special meeting of the Governors of the Dispensary was held to elect a Surgeon in place of Mr. Drew, resigned. There were three candidates. The votes were declared as follow:—Mr. Wm. Saville, Wakefield, 31; Mr. Joseph H. Stone, Wentworth, 27; and Mr. Garrard, Plymouth, 18. Mr. Saville was declared duly elected. A vote of thanks was unanimously awarded to Mr. Drew, the retiring Surgeon, for the attention he has paid to his duties since his appointment, for having effected great economy in the management of the Institution, and for having introduced several improvements in its management. It was also determined to present Mr. Drew with some tangible proof of their approval of his services, and the Committee were empowered to select the most suitable memento.

COMPULSORY VACCINATION. The new act to extend and make compulsory the practice of vaccination, was published on Monday last, and from this new law it appears that parishes or unions, if need be, are, within six weeks of the passing of this act on the 20th inst., to be divided into districts, for the purpose of vaccination, and places are to be appointed for performance of the operation. The parents and guardians of children born after August 1st, 1853, are to have such children vaccinated within three or four months after birth, and the children are to be taken for the inspection of the medical officer on the eighth day after the operation, to ascertain the result of the same. Should the parents neglect to have the child vaccinated, they are liable to a penalty not exceeding twenty shillings.

MR. BRANSBY COOPER. The funeral of this gentleman took place at an unusually early hour on Thursday morning (Aug. 25), in a most unostentatious manner, in strict accordance with the wishes of the lamented deceased, at St. Martin in the Fields, the Right Hon. the Secretary of State having permitted the family vault to be opened for that purpose; this church being one of those in which interments are prohibited. The procession left the late residence of Mr. Cooper at half past eight o'clock, headed by the medical and surgical staff of Guy's Hospital, and followed by the immediate relatives and friends of the deceased, including the few students of the hospital remaining in town. It may not be generally known, that John Hunter is buried in the same vaults. Mr. Cooper delivered the annual oration in memory of the founder of the Hunterian College of Surgeons, in February last.

TESTIMONIAL TO A GENERAL PRACTITIONER. On July 9th, a deputation of friends and patients waited on B. Parkerson, Esq., surgeon, of East Dereham, and presented him with a service of plate, value about £120. The service consisted of a very large and handsome salver, kettle with stand, tea and coffee-pot, etc.; and the occasion of its being presented was that the recipient might carry out with him to the far-distant colony for which he is bound, some sort of proof of the high esteem in which his professional services have been held for the last twenty-six years, and at the same time to express the general feeling of deep regret at his approaching departure. Mr. Parkerson has since set sail for Canterbury, New Zealand, in the ship, *John Taylor*, to which he was appointed the surgeon-superintendent.

REQUESTS. Mr. John Simmitt, late of Lower Norwood, has bequeathed £2000 to be equally divided among the following medical charities:—St. Mary's Hospital; the Royal Sea Bathing Infirmary, Margate; East London Consumption Hospital; and the Royal Free Hospital. The executors appointed to carry out the benevolent intentions of the donor, are John Gay, Esq., surgeon to the last mentioned institution; John Combe, Esq., of Staple's Inn; and Mr. Bagner, of Bishopsgate Street.

UNIVERSITY OF EDINBURGH: PASS LIST. Names of gentlemen who obtained the degree of Doctor of Medicine in July 1853:—Andrew Mercer Adam, Scotland; John Henry Aldridge, England; Thomas Anderson, Scotland; Charles Ashenheim, Scotland; John Beddoe, B.A., England; Peter James Berryman, New Brunswick; William Weddel Bizset, Jamaica; Jean Valleton de Boissière, Trinidad; Henry Breton, East Indies; James Lundin Brown, Scotland; Robert Bruce, Scotland; Wm. Bryce, Ireland; Merrick Lloyd Burrows, England; Robert Graves Burton, Canada; Guillaume Chasseaud, Smyrna; Robert Christie, Canada; William Alexander Clugston, Ireland; Frederick Cock, England; James Collinge, England; James M'Haffie Cowan, Scotland; James Allan Currie, M.A., Scotland; Allen Dalzell, Scotland; John Dickson, England; Arthur Dupuy, East Indies; Charles Dwyer, Ireland; George Fair, Scotland; David Finlayson, Jamaica; Francis S. B. François de Chaumont, Scotland; Dunoon A. C. Fraser, Scotland; John Gray, Scotland; David Greig, Scotland; Alexander Guthrie, Scotland; Thomas Wright Hall, Brazil; William Hamilton, Ireland; Tom Smith Hewitt, England; David Hood, Scotland; Robert Fawre Hutchinson, East Indies; Cornelius Inglis, England; James Jardine, Scotland; John Johnstone, Scotland; Arthur Trefusis Jones, Malta; William F. O. Kay, Scotland; Edwyn John King, England; Edward Wickstead Lane, M.A., Canada; Joseph Law, England; James Henry Losh, Scotland; Edward John Longton, England; Alexander John Macarthur, Scotland; Francis Robert Macdonald, Scotland; James W. N. McKay, Scotland; John Matthews, England; William Somerville Millar, Scotland; Thomas Miller, Scotland; David Milroy, Scotland; Robert Moir, Scotland; Emilius Rowley Nicholson, England; Francis Hugh O'Donel, East Indies; Joseph Fructuoso A. de G. Otorio, M.D., Coimbra, Portugal; Neville Gray du Vernet Parker, New Brunswick; George Clark Pirie, Scotland; Salvator Aloysius Pisani, M.D., Univ. Malta, Malta; William Overend Priestley, England; David Ramsay, Scotland; David Watkin Roberts, Wales; William Tindal Robertson, England; Francis M'Manus Russell, Canada; Richard Sarell, Constantinople; William Henry Scott, Scotland; Eleazar Sherwood, England; James Sinclair, Berwick-upon-Tweed; Tom Speak, England; James Frederick Stewart, Scotland; David Halket Sterling, Scotland; James Petrie Street, New Brunswick; William Taylor, Ireland; Henry Titterton, England; John Turle, England; Edward Penrose Twyford, England; Henry Richard Veale, England; Henry Hannotte Vernon, England; Robert Wailes, England; Patrick Heron Watson, England; Thomas Robert Williams, England; Christopher Young, England; James Young, Scotland. The four prizes annually given were awarded to Dr. William Bryce, for his dissertation on the Medical Topography of the Lake District of the North of England; to Dr. Allen Dalzell, for his dissertation on the Integumentary Appendages; to Dr. W. O. Priestley, for his dissertation on Pelvic Cellulitis, and the Fascia of the Pelvis in the Female; and to Dr. John Turle, for his dissertation on Quinine.

KING'S COLLEGE UNIVERSITY, ABERDEEN:—PASS LIST. Gentlemen admitted Doctors of Medicine on August 12th, 1853:—John Campbell, E.I.C.S., Bengal; Alfred Richardson, London; Charles G. Hewson, Devonshire; Henry Callaway, London; Joseph Kidd, London; Charles C. Hayman, West Malling; Perry Dicken, Ashby-de-la-Zouch; Edward H. Greenhow, Tyne-mouth; William R. E. Smart, R.N.; John S. Taylor, Liverpool; John V. Hawkins, London; Joseph Nash, Box, Wilts; Charles H. Payne, London; William Smith, Weyhill, Hants; James R. Hancock, London. At the same time, the degree of M.B. was conferred on Henry Polson, Old Aberdeen, and John Ross, Aberdeen.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention, and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXXVI.

LONDON: FRIDAY EVENING, SEPTEMBER 9, 1853.

NEW SERIES.

ADVERTISEMENTS.

Three lines and under	-	-	-	£0	2	6
Every additional line	-	-	-	-	0	6
Half-a-column	-	-	-	-	1	10
A whole column	-	-	-	-	2	15
A page	-	-	-	-	5	5

A line contains ten words, so that any one can calculate the cost of an Advertisement.

Advertisements ought to be delivered at the office on the Wednesday preceding publication, and paid for at the same time.

Post-Office orders are to be made payable to THOMAS JOHN HONEYMAN, 37, Great Queen Street, Lincoln's Inn Fields, London.

THE MEDICAL SCHOOLS. In compliance with the wishes of several correspondents, we propose, on the 23rd September, to give, in the body of the Journal, a condensed view of the prospectuses of the various medical schools which have appeared in our advertising columns, or which may appear on or before that date.

DISCIPULUS is requested to communicate his name and address.

FINANCE:—THE JOURNAL AND THE TRANSACTIONS.

If associations have ever possessed great power, it has been in virtue of the union of many minds all tending in one common direction, and aiming at one common end. The stupendous achievements of past ages, which are only rivalled by the mechanical triumphs of our own day, show what even untutored physical strength could accomplish; and to-day the physical impossibilities of what we facetiously call the dark ages have succumbed to the associations which have developed by contact that faculty of mind which has in its vocabulary no such expression as *impossible*, and which has made even time and space but accessories to its strength.

Banded together in the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION for no selfish purposes, seeking in no commercial spirit for profit or for gain, we too can look trustfully on, believing that, from the jarring elements which surround us, there shall arise a fair future to redeem medical science from many of the extraneous evils which prevent its progress, and hinder its advance. Our Association, though it may appear accidentally in a trading guise in returning to its members a tangible equivalent for their subscriptions, can, collectively, and we trust also individually, be actuated but by one motive, and be animated only by one generous impulse. It seeks, in raising and elevating the status of the medical profession, to relieve the destitute, to alleviate the pangs of the suffering, to bring joy where sorrow but now was imminent, and to chase away from the domestic hearth of our friends those dread shadows of death which disease had impended over their dear ones. So indissolubly are united together the best interests of our common humanity with the rightful practice and progressive improvement of our profession, that, even more than ourselves, the public are interested in all that tends to advance our knowledge or increase our facilities for good.

But much that we could accomplish, as an Association, would be lost, had we no power, by the free interchange of opinion, to correct our own impressions, and to fix these impressions on the minds of others. The Promethean spark which is to light up for the world's good many a slumbering and latent gift or discovery would never be struck, did we not afford to our fellows the fullest opportunity of knowing and making known all the varied incidents of life and death which bear upon the progress of medical science.

It must be evident that, with members scattered over all parts of the United Kingdom, and even in foreign lands, this can be accomplished only by an organ of communication to which all may have free access, and from which they may learn the opinions and be acquainted with the facts which, in the progress of discovery (to-day so active), are either developing or developed. It is thus that a weekly journal becomes an indispensable necessity, if we would fully and freely accomplish all that we have, as an Association, clearly placed within our reach. We thus become, to a certain extent, in our character of publishers, a trading firm carrying on an accidental commercial enterprise; not rivalling or precluding the necessity of other publications, but supplying a hiatus they could not fill; and, we trust, each week binding more closely together the ties which unite us, both as members of a liberal profession and as an association promoting the good, increasing the power and knowledge, and elevating the status of medical men throughout the world.

We cannot therefore pass over the important discussion on the Journal, at the anniversary meeting at Swansea, without appending a few remarks to illustrate the position so incontestably proven by the gentleman who moved the adoption of the Report of the Journal Committee; moreover, we are well assured that, in an Association like our own, good, and good only, can accrue from the possession by the members of the most complete knowledge on all points connected with its constitution, management, and finance. In a new undertaking, it is but right that the most scrupulous inquiry should be instituted into its condition and prospects; and as very limited means are placed at our disposal, it is necessary to be convinced that expenses are kept within the boundaries of income. Peculiarly placed as we are, in having a large guaranteed circulation, and having beyond that comparatively few sales, (from the fact that persons desirous of purchasing the Journal become members of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION,) we can still fall back upon those general principles which in ordinary business decide the success or failure of any commercial enterprise.*

For this purpose, we may illustrate our present position by viewing the members of the Association as subscribers to a Medical Journal conducted in the ordinary manner, and thus estimate the revenue of the Journal issued to its

* The extra-Association sale of the Journal is chiefly to colleges, societies, and public reading rooms.

two thousand subscribers at 7d. per week each. We find that the total receipts from this source would be £3,033:6:8. Now, assuming that the whole amount of the subscriptions of members went to pay for the Journal expenses, *which is far from the case*, there would then, viewing it as a commercial undertaking, be a profit to the subscribers on the year of £1,000, or upwards of 30 per cent.: no inconsiderable proof of the sound principles upon which the business has been hitherto conducted, and clearly demonstrating the fact that, if the medical practitioner desire a journal, he can, by joining the Association, obtain one, with all the other advantages of membership, at a large saving to himself. But we turn to the other and relative side of the question; and here we find the total cost of production, chargeable to the subscriptions of members, to have been, for the last six months, £856:16:6, or less than 4d. per number for each member. Then, deducting, as we fairly may, from the expenditure of the next six months, the amount of expenses connected with preliminary arrangements, and hence no longer necessary, we calculate the cost of the Journal at £758:9:7, or 3½d. per number for each member. It will thus be found that the clear gain to the Association on the whole twelve months, provided a journal be supplied (and what practitioner would be content without weekly intelligence to keep him *au courant* with the progress of medical science?), is not less than fifteen shillings per member. It will moreover be found that, while the estimated cost for the first twelve months amounts to £856:16:6 ÷ £758:9:7 = £1,617:6:1, the receipts, if the members were subscribers at 7d. per week, instead of paying or promising to pay £1:1 per year, would amount, as before stated, to £3,033:6:8, which, with a handsome amount allowed for contingencies, would make the Journal property to be worth, at a fair calculation, £1,000 per annum.

But it must be borne in mind that, the expenses of some Branches being paid out of the subscriptions of members, leaves from these Branches only 18s. 6d. as the available yearly amount to be devoted to general Association expenses: and from this, £200 has been during the past year voted for Medical Reform, besides many other incidental expenses of which the members derive their full advantage. It is thus evident that for their annual subscription the members obtain a Journal worth 30s. per ann., and all other advantages derivable from membership; and thus, by that *esprit de corps* which supports the Journal and enables it to be conducted at its present low rate of yearly charge, a profit of at least £1000 is divided among the members.

Viewing it merely as a matter of finance, it must, therefore, be evident to all, as it appears distinctly proven to us, that it would be idle to expect (much as we join in the wish) a volume of yearly *Transactions* to be issued to the members at no increased rate of subscription. We are far from saying that there should be no further issue of those elaborate papers on topography, statistics, etc., which have from time to time appeared in our *Transactions*. This indeed we should regret, from the loss which would accrue both to the standing of the Association, and to the reputation of some of its individual members. But we think that the publication of these papers must either be paid for from a separate and voluntary subscription, or be printed in the pages of the Journal. To either of these plans we can conceive objections; but, in our present financial position,

we can see no other path pointed out by a prudent forethought and a wise expenditure. There is, be it remembered, a limit to the capabilities of an annual guinea. We have recourse to these modes of argument and illustration, because they must speak for themselves to persons acquainted with the business transactions of life.

There is one point, in connexion with this subject, which, however painful, is of so much importance, as testified by the tone of the meeting at Swansea, as to demand from us more than a passing notice. Of the subscriptions which should have been paid in advance, there are at this time £1,093 in arrear! or so much of this large sum as may not have been paid to the General or District Secretaries since the annual meeting. To prevent in future such an accumulation of arrears demands not only the best thoughts, but the most earnest endeavours, of the true friends of the Association. It is the want of this money which often cripples our energies, and interposes a main obstacle to our progress. We are in receipt of many proposals for the recovery and prevention of these arrears; but among all our correspondents there is a general feeling that the name of no gentleman should be enrolled, neither should he receive the Journal, until his first subscription has been paid; and that the names of all members who have suffered their subscriptions to be in default for more than twelve months should (after neglecting for one month to answer a circular addressed to them by the Secretary, stating the fact) be liable to certain fines, which if not paid should in time lead to a suspension of the Journal. We would suggest to our friends, the district secretaries, a methodical and constant application for arrears, believing as we do that arrears arise rather from the pressure of professional engagements than from any intention of avoiding payment.

Here the extension required in our Branch organization demands notice; but this subject we must reserve for another article.

THE FEES RECEIVED FROM CLUB PATIENTS.

THE rates of payment which medical men receive from clubs vary considerably. A few clubs belonging to the Order of Odd Fellows pay, we believe, 7s. 6d. per patient per annum. These, however, are exceptional instances; and, if the truth could be arrived at, we think it would be found that 3s. per patient represents at most the average sum received by the whole profession from club practice. We know of one gentleman who holds not less than twenty-five clubs in a manufacturing district, the payment being scarcely 2s. 6d. per annum for each person; and of another practitioner, who, having a club which pays from £14 to £15 yearly, makes not less than 1,000 visits for that sum, in addition to the medicines supplied.

This state of matters is very painful to contemplate. How far it is to be met and remedied, is a great and difficult question; for we fear that, in some cases, the clubs really do offer all that they can afford to give. The poor stocking manufacturer, or Northampton shoemaker, who, with aching eyes, aching hands, aching heart, works for twelve long hours daily for that 1s. 6d. or 2s. which has to purchase the necessaries of life for six or seven helpless innocents, finds even the sum of 2s. 6d. per annum a serious item in his expenditure. In this matter important services rendered for the unimportant sum

not the question to be considered most, but the capabilities of the poor man to pay for *any* service. Food, raiment, and house shelter, take the first place in every man's affairs; and the purveyor, the clothier, and landlord, are considered by all, and very naturally too, before the doctor, whose good offices are only occasionally in requisition. We must not shut our eyes to these simple facts, even though they tell against our own interests; neither must we forget that club practice, with all its evils, is vastly superior to union practice—superior in payment by four or five times; for every club patient pays, as a general rule, three times more than the average sum paid for each union patient, and need not necessarily require attendance in return; and superior also, in that the interference of boards of guardians, and the oppressive insolence of relieving officers, are not present, to annoy and sicken the practitioner. Still more, we know that, in numerous instances, clubs insure to the professional man a remuneration for his services, which, however small it may be, would be nothing at all but for them, inasmuch as the club patient would either become a pauper patient, or be attended out of mere charity.

Are there then no possibilities of effecting a reform in the club system? We think there are. If the government could but be made to move in the matter of union medical appointments, and to make them more remunerative, the club fees would rise at once; for the club patient, being always anxious to avoid the "parish doctor", would give a little more than the average amount of union payment to secure his own selected private medical man. We cannot too earnestly urge this point on the government.

Again, we might carry on an internal reform, in reference to the practices of those who, being well able to pay for medical services, join a club, to insure cheap medical attendance. The profession, one and all, should stand out against this dishonest encroachment; and we believe that, were the subject well considered at the Branch meetings of the Association, a firm stand might soon be made, and then the proper remedy would soon follow.

Lastly, the medical man cannot too often or too earnestly point out to the members of clubs the impropriety and folly of having so many separate and rival club institutions. At the festivities of clubs, no sentence is painted on the banners in larger letters than the old motto, "Let friendship reign while here we stay; let brotherly love continue". In the management of these societies, no motto is more thoroughly forgotten and disregarded. In the club system, "unity" ought to be a first law; it would strengthen and prolong the life of the system, and, in so doing, would enable the benefited patient to pay his doctor a fee that should not only secure better attendance, but excite that just pride which every true Englishman feels when he knows he has paid for that which he has obtained.

MEDICAL STUDENTS AND THE GOLD DIGGINGS OF AUSTRALIA.

THE *Times* makes the journal at the diggings of a Guy's student the text for a leading article; and both the journal and the comments contain matter for very serious consideration in these days. The medical student, before he has passed his examinations, starts for the diggings in Australia with three others, one designed for the bar, one for the church, and one for surveying. They have some money, as they buy a horse and cart, and take tents and implements for work; but they are taken in with the horse, they cannot get any

distance, they return disappointed, and break up their party. The surveyor gets to survey the roads; the young surgeon tries in vain at all the chemists' shops to find employment, but they will not take him, as he is a surgeon's pupil, and they want a chemist's apprentice. He thinks himself fortunate to get a job of whitewashing for four days, and on the profits buys some peaches and apples which he hawks in the street. Whilst so engaged, he sees two Guy's students working on the wharf as labourers; and he says, notwithstanding his own humble work, "Poor fellows, I did pity them!" Hawking fruit did not answer long, and, with a friend's little capital, the two set up a stall in the market to sell boots and shoes, books, and clothes. At the end of seven weeks, they were poorer than when they began, and then resolved to start for the diggings. Here the same want of success followed, and, when the medical student ended his journal, he was a carter, and driving a horse and dray about Forest Creek Diggings. His father sends his journal to the *Times* as a warning.

This, from what we hear from those who have been there, is the common fate of young men who, bred to intellectual professions here, go out to attempt to gain gold in an occupation only fit for "navvies" and strong labourers. They fail there just as they would fail here, if they were to hire themselves for the making of railway embankments, or the construction of docks. But the rush of youths of this description to Australia is a matter of serious reflection for those who have to decide on the occupation of their sons. It must be recollected that, during the last fifty years, the inhabitants of Great Britain have doubled in number, and, as this increase goes on, the increased competition from numbers must be still more severe; and, as education and mental activity increase also, there will be more of the competition of talent. It will, therefore, be much more necessary than it ever has been that youths should be brought up to those occupations for which they are most fitted, and that those who, from organisation, deficient abilities, and want of natural energy, are not likely to make their own way in a profession which requires vigour and talent, should not be introduced into it. It was one of those visions of the future which the German poet Goëthe foresaw and practised in his Utopia, that every youth should, as the world improved, be brought up to do that for which nature fitted him; and that such anomalies as we now see, when a man whose chief delight was in making locks, became an inefficient king, will cease. We are far from such a Utopia; but we are nearer than we ever were to such a state of things, when each man will be valued for what he can actually effect, and when the world will more accurately know what is in each man's power to do. As a general rule, a youth cannot choose wisely his own calling in life, as he has neither the requisite knowledge of himself nor of the world; and a permission to make such a choice against the convictions of his parents is the most cruel liberty he can have. Those, therefore, who ought to decide these matters have a heavy responsibility; and the numbers who are brought up to medicine, and who sooner or later give it up, and the still larger number who sorely regret that they ever entered the profession, prove that a warning to greater circumspection in the first decision of a calling is necessary.

With regard to the question which is often asked, as to the propriety of medical students going to Australia, for the sake of actually digging gold, there can be, with our

actual experience, but one answer. It is a manual labour which requires the hardest bodily toil, and only those should go who are fitted by their bony and muscular organisation to get their bread as labourers. As to the other question, whether it is advisable for young surgeons to try Australia as a field for medical practice, we cannot do better than quote from the able leader of the *Times*:

"If a young man has made such good use of his time—has shown such undoubted ability—has made such friends—has such an opening, and so much money as to set him up respectably, and procure him a good partnership or independent practice—in a word, if he is likely to get on well in this country, and has not the same grounds for believing that he will get on well in Australia, certainly he had better remain where he is. He has no adequate reason for moving, and would be only throwing away a very enviable position. As a general rule, a man who can get on in England had better not go to a colony. But we should like to know how many of the young men who pass at the College of Surgeons or Apothecaries' Hall have such prospects before them as we have described. Many have no extraordinary talents, no money, no friends, no position, no opening whatever; and have just as much to look about for a place where they may be permitted to squat in this country, as if they found themselves shipwrecked off some headland on the coast of Victoria. They have to take a house or a ground floor, put a brass plate on the door, perhaps offer "advice gratis" at certain early hours, perhaps form an unholy alliance with some aspiring chemist, get credit from some tradesmen, descend from one dodge to another, and, perhaps, after some years of this miserable work, compound with their creditors, and decamp and try the same game elsewhere. Others, with rather more pretensions, try a higher game, publish, canvass for places, and so push on through many a year of poverty. Now, if a young surgeon has no better prospects than these, he may just as well go to Melbourne, where he will find rather more elbow-room, and where he may become an Australian Astley Cooper."

To sum up what has been said. Much greater caution should be used in permitting youths to enter the medical profession; and those who have got through their education, but have neither an opening nor prospects in this country, may try Australia as surgeons, though not as gold diggers. The attraction which during the last two years has deluded so many men, without sufficient muscles and bones, to attempt labourers' work at the diggings, has drawn a large number of its victims from the ranks of our profession, and, we fear, will continue to draw many more, notwithstanding the bitter experience which has been proved on so large a scale.

EDINBURGH BOTANIC GARDENS. We understand that the government have consented to make provision in the next year's estimate for the extension of the palm-house in the Botanic Gardens, the insufficient size of which was brought before them some time ago.

M. RICORD. An authorisation appears in the *Moniteur* permitting M. Ricord to wear foreign orders of knighthood from Russia, Belgium, Spain, Sweden, and Sardinia.

NEWS AND TOPICS OF THE DAY.

POST MORTEM EXAMINATION OF THE BODY OF THE LATE MR. BRANSBY COOPER. Examination of the remains of B. B. Cooper, Esq., in the presence of Messrs. J. Birkett and Alfred Poland, August 20th, 1853, at 8 A.M., about forty-one hours after death.

At the root of the tongue, and most on its right side, was a deep excavation, covered over by the cortex of the organ, which seemed to form flaps to the hollow. Around this excavation, the tissues of the tongue itself, as well as the muscles about the os hyoides, were infiltrated with the elements of carcinoma.

Several enlarged lymphatic glands existed upon the right side of the neck, all infiltrated with carcinoma. From one large gland, and from another smaller, when cut, a yellow, tenacious, mucopurulent fluid came away. The parietes enclosing this fluid was carcinoma.

The trachea and bronchi contained fluid blood, as well as the air cells of the lungs, and patches of cells infiltrated with blood appeared upon the surfaces of both the lungs. The tissue of the lungs was healthy, and not a single pleural adhesion existed on either side.

The heart was small, and its muscular tissue thin and pale. The valves were healthy.

The stomach contained imperfectly masticated food, and much blood coloured fluid.

The tissues of the alimentary canal were healthy.

The liver was rather small, soft, and congested with blood.

The pancreas was not diseased.

The spleen was extremely contracted and corrugated, and of a dark, almost black, hue.

Both kidneys were congested with blood, soft, and easily separable from their proper tunics.

In the cavity which existed in the tongue there were a few clots of blood, and as this was the only ulcerated surface, it may be presumed that the hæmorrhage proceeded from a perforation in the right lingual artery, or of one of its branches.—*Medical Times*.

THE NEW ACT ON CHARITABLE TRUSTS. The Act for the Better Administration of Charitable Trusts has been issued. There are, we find, sixty-eight sections in the Act, and it took effect on the 20th instant, when it received the royal assent. The Board is to be called, "The Charity Commissioners for England and Wales". The work of the Board is defined by the ninth section, which enacts, that "it shall be lawful for the said Board from time to time, as they in their discretion may see fit, to examine and inquire into all or any charities in England and Wales, and the nature and objects, administration, management, and results thereof; and the value, condition, management, and application of the estates, funds, property, and income, belonging thereto; and the said Board may cause examinations and inquiries in relation to the matters aforesaid to be made and prosecuted by their inspectors, acting together or separately, in such cases and at such times as the said Board may think fit, and all such inspectors shall, from time to time, report their proceedings to the said Board." Powers are given to the Board to require accounts and statements of charities. The inspectors may examine witnesses on oath, and persons refusing to render accounts, or to give evidence, are to be deemed to be guilty of a contempt of the Court of Chancery, and may be committed by such Court on summary application by the commissioners to the same, and be ordered to pay the costs, if the Court shall so direct.

ORIGINAL COMMUNICATIONS.

NOTES ON THE VINEGAR-PLANT.

By SPENCER THOMSON, M.D.

WITHIN the last two or three years, there have appeared from time to time, in various journals, medical and general, notices of what is called the "vinegar-plant", a peculiar fungoid development, now extensively used in many parts of the country for the domestic manufacture of vinegar. Seeing this mode of making vinegar in frequent operation in a cottage I had occasion to visit professionally, I was induced to make a few experiments and observations, with a view to ascertain the nature of the vegetable growth, and, if possible, its mode of action; the interest being the greater, as apparently from the queries respecting it, the vinegar-plant is an unknown object of curiosity to some of our scientific men.

The plant itself, when well developed, resembles nothing so much as a thick unbrowned pancake; its consistence is very tough and leathery, and its form and diameter are dependent on those of the vessel in which it grows. When young, the growth is thin and gelatinous looking.

The ordinary mode of making vinegar by means of the vinegar-plant is very simple. It is thus described:—"Put the plant—a young one—in an earthen jar, add to it half a pound of the coarsest moist sugar, and half a pound of treacle, with five pints of milk-warm water; cover it lightly over, so as to keep out the dust, but not the air; and then put it in a moderately warm situation; there let it remain seven weeks, not disturbing it more than you can help. At the end of that time, pour off what is now the clear vinegar, and keep it in well corked bottles for use. Again, add to the plant the same quantity of water, sugar, and treacle, as before. At the end of the second seven weeks, the plant will have become like two thick pancakes, and the two parts may be easily divided, care being taken not to tear either the old or the new plant. If the plant is exposed to the cold, or kept too long out of the liquid, it will die."

By the domestic makers of vinegar by means of the plant, it is insisted upon as a necessity that a plant should be present in the saccharine solution: this, of course, is an error; but, on the other hand, it is equally erroneous to assert that the plant is simply an adventitious growth, which is developed during the formation of the vinegar, but which has nothing to do with the process. In my first experiment, I placed in a dark situation, of 75° average temperature, three glass vessels of saccharine solution, made with treacle and sugar, in the proportions above named. To one vessel I added a young vinegar-plant, which immediately sank to the bottom; to another, a small quantity of yeast; the third was left without any addition. In the course of two or three days, as might be expected, in the solution containing yeast, active alcoholic fermentation was going on; in a few days more, this had subsided, giving place to acetification, which, by the sixteenth day, was complete, the solution being converted into strong vinegar. At the end of a week, the solution containing the vinegar-plant smelled like sour milk; the plant added to it still remained at the bottom of the vessel, but a new plant had formed on the surface of the liquid. In the simple solution, no apparent change was to be detected. At the end of three weeks, the report is: "Solution with yeast converted into strong vinegar, and bearing on its surface a gelatinous looking growth, resembling the vinegar-plant, but more brittle, and less leathery. Solution containing vinegar-plant acid, but not strongly so, bearing a fresh well formed plant on its surface. Simple solution scarcely acid, also bearing a gelatinous plant."

This report was on April 22nd; the same day, five glass vessels of the sugar and treacle solution were taken. Into

No. 1 was put the fresh vinegar-plant, formed from the plant used in the first experiment; into No. 2 was put the plant formed on the surface of the acetified yeast solution; into No. 3 was put the plant formed on the surface of the simple solution, all these being obtained from the first experiment; into No. 4 was put a small portion of yeast; No. 5 was left a simple solution. To the above were added two vessels containing each a solution of pure white sugar, in the proportion of two ounces to the pint; one was left simple; to the other a vinegar-plant was added. The seven vessels were placed in a dark situation, of average temperature, from 55° to 65° F. At the end of three months, all the solutions of coarse sugar and treacle were very acid, but that to which the yeast had been added was most strongly so: all five bore on their surfaces well formed plants, and in the first three, to which plants—from yeast, vinegar-plant, and simple solution of first experiment—had been added, the old plants lay unchanged at the bottom of the vessel. The simple solution of white sugar was apparently unchanged; that to which the vinegar-plant had been added was very distinctly acid, but weak compared with the brown solutions; and on its surface it bore a very fine transparent plant, loose in structure, and very different from the compact leathery mass growing in the coarse solutions. When lifted out of the solution, this plant resembled nothing so much as the vitreous humour of the eye, both in appearance and texture. In this solution, as in the others, the old plant, which had been added in the first instance, lay at the bottom of the fluid unaltered.

The question arises, What is the vinegar-plant? If a portion of it be placed under a high magnifying power, 600 diameters, it will be found to consist of spores and minute cells, in various stages of development, lying among interlacing and branched filaments; in short, the spores, cells, and filaments are precisely similar to those seen in the vegetative and mycelium stages of a common mucar, or of the penicillium glaucum, only they are more minute. The vinegar-plant, therefore, is simply an expanded thallus, formed by an aggregation of spores and cells entangled in the filaments developed by the budding forth of the latter; the whole apparently being connected by mucilaginous matter. The form and structure—if it can be so called—of the thallus is apparently determined by the nature of the medium in which it is developed.

Of course there could be no doubt beforehand of the conversion of the coarse saccharine solutions into vinegar, without the addition of yeast, of vinegar-plant, or of any other ferment; their own azotized components in their unpurified condition being sufficient for the purpose, especially under the higher temperature of the first experiment; but the question arises, how far the presence and growth of the vinegar thallus influence or assist the elementary changes by which the saccharine is converted into the acid. As mentioned at the commencement of this paper, it has been asserted that the presence and growth of the vinegar-plant is simply adventitious, and that it exerts no influence in the acetifying process. The error of this supposition is proved by the experiment with the solutions of refined sugar; for, whereas the simple solution remained unchanged at the end of three months, that to which the vinegar thallus had been added was distinctly acetified, this being in my opinion sufficient to prove that the fungoid development or thallus known as the vinegar-plant, is the distinct acetic ferment, capable of determining the acetic fermentation in saccharine solutions, by a power in strict analogy with that by which the torula cerevisiæ or yeast ferment excites the alcoholic fermentation. Like the torula cerevisiæ, the vinegar-plant appears to be capable of development, *de novo*, in saccharine fluids containing azotized matter, provided external circumstances are favourable. It would also appear, that although, like the yeast-plant, its presence may not be absolutely necessary for the excitement and perfecting of its peculiar fermentation it does exert a certain amount of catalytic action upon the components of the saccharine solution, thereby determining and aiding their conversion into acetic acid. I am inclined to think,

* *Lancet*, 1853, vol. ii, p. 303.

moreover, that the presence of the vinegar-plant will give rise to the formation of acetic acid in a saccharine solution, at a lower temperature than that at which the change could take place, were the acetic ferment absent.

There is, however, one remarkable difference between the mode of action of the alcoholic and acetic ferments. As the process of alcoholic fermentation consists of interchange of elements within, and of escape of carbonic acid from the fluid undergoing the change, the yeast torula seems to be in active vegetation as truly throughout the whole fluid, even at the bottom; its greater collection at the surface being simply due to its being carried upwards by the escaping gas. The vinegar-plant, thallus, or ferment, on the other hand, is active only on the surface of the fluid. Old plants once submerged—at least in the saccharine solutions used in the making of vinegar which had a sp. gr. 1.040—do not rise again, but continue without change or increase at the bottom of the fluid, whilst a new plant forms on the surface. How far that surface growth of the plant may be connected with the absorption of the oxygen necessary for the acetifying process, it is, at present at least, impossible to say.

It may be asked, how comes the vinegar thallus in a solution to which no spore or spawn from another plant had been added? It is, I believe, a fungoid development, the form of which is determined by the nature of the medium in which it vegetates; but when it is developed, I believe it is capable of assisting in, and predisposing to those elementary changes and interchanges which take place in the acetous fermentation, and perhaps of aiding the absorption of oxygen necessary for the process. With such a view, the originating spores may have been those of the sugar fungus, or of some of the common moulds. Indeed, if vinegar with a growing vinegar-plant on its surface be exposed to the atmosphere for a considerable length of time, the vinegar thallus passes into a crop of mould. Dr. Carpenter* observes, "of all the protophytes it may be remarked, that the conditions under which they are developed, produce a considerable modification in their mode of growth, and may even effect such a change as to obscure their characteristic 'nisi'". The history of the vinegar-plant appears to corroborate this idea. Throughout this paper, the vinegar thallus has been spoken of as a fungus; and if it be characteristic of the fungi that they are most readily and perfectly developed in situations where azotized matter in a state of decay or change furnishes them with a free supply of carbonic acid and ammonia, then must the vinegar plant belong to them, for we have seen that in the solution of refined sugar from which azotized ammonia-yielding elements had been removed by purification, little, if any, development took place, and the acetification was weak. This latter fact, moreover, proves that the catalytic action is dependent upon the growth of the thallus; for were it not so, were it simply occasioned by the presence of a thallus, there is no reason why the acetification of the pure sugar solution should not have advanced equally with that in the unpurified solutions, each having a similar old plant introduced into them. Again, the vinegar thallus developed on the surface of the saccharine fluid must, necessarily, have continued fresh supplies of whatever element is most essential to its development from the free communication between the particles of the fluid, and as long as the fluid can furnish the element or elements, it continues to flourish; if, however, as stated above, the growth of the thallus be permitted to continue upon a portion of vinegar exposed to the atmosphere for a considerable time, probably from exhaustion of the element required, the vinegar plant degenerates into simple mucar. Similarly, mucar or mould forms on the surface of a solid mass of cheese or of sugar preserve. There can be no interchange of particles as in the fluid, consequently the outer layers of the supporting medium can only furnish the food for growth. Is it that the vinegar thallus requires a more ample supply of some particular element of saccharine and at the same time azote-yielding fluids or sub-

stances, for its development than is requisite to support the growth of the moulds?

The observations in the foregoing paper I offer rather as suggestive than otherwise. The subject is one which does not appear to have undergone any special investigation, and my chief object is to direct to it the attention of those who have more leisure than myself to devote to such inquiries.

Haunton, Burton-on-Trent, August 25th, 1863.

CLINICAL ILLUSTRATIONS OF SOME DISEASES OF THE ŒSOPHAGUS.

By C. E. REEVES, B.A., M.D.

[Continued from page 704.]

SPASMODIC STRICTURE.

STRICTURE FROM AFFECTION OF THE STOMACH. CASE I. Mr. Abernethy relates the following case.* A lady had for many years suffered from what her medical attendant supposed to be organic stricture of the œsophagus. She was now reduced to such a state, that food could be taken only in very small quantities at a time, large quantities of liquid being necessary to enable it to descend into the stomach. He was requested to pass a bougie, but he declined to do so, as the disordered stomach, furred tongue, and tender epigastrium, led him to suppose that it was only sympathetic. Attention to the stomach and bowels soon gave relief to the difficulty in swallowing, and she ultimately got quite well.

CASE II. A young man,† of florid complexion and full habit of body, after walking a considerable distance on a very hot day, was suddenly taken with severe pain at the orifice of the stomach, with great difficulty in breathing, and inability to swallow. He was cured by copious extraction of blood. In the following winter, a slight return, which yielded to purgatives. In the following spring, he was suddenly awakened early one morning with the pain and other symptoms. Bleeding gave him great relief, but only for a short time. He was again bled, by which he was permanently relieved.

CASE III. A female, aged 69,‡ had suffered frequently from pains in the throat, descending at times down to the stomach, with great difficulty in swallowing. A bougie met with some slight obstruction at the lower part of the pharynx, but gave great relief to the obstruction. Five days afterwards, a pain seized her at the epigastrium, and obstruction for the first time manifested itself at the entrance into the stomach. She sank soon after. The stomach was thickened throughout, except for one or two inches near the pylorus, and would not contain more than six ounces of fluid.

CASE IV. A man, aged 45, was, says Monro,§ under the care of my father, Dr. Keith, Mr. Wardrop, and Mr. G. Bell; he had been suffering from dyspepsia and pain in the stomach for two years, and for the last three months from occasional attacks of spasmodic stricture. In October 1810, the stricture became more troublesome, particularly at breakfast. On October 17, a bougie was passed, an obstruction being felt quite distinctly; but it was not relieved until the 9th of November. A cold reproduced the dysphagia, which yielded in the course of a few days to the introduction of the probang. He sank the following May, with all the symptoms of malignant disease of the stomach. The œsophagus was found quite healthy, the stomach distended with dark coloured fluid, and adhering to the liver, a fungous ulcer existing at this point.

STRICTURE FROM AFFECTIONS OF THE LIVER. Portal (*Maladies du Foie*) mentions a case of hepatitis, attended by another physician and himself, where stricture of the œsophagus existed.

Frank met with it in a case of inflammation of the superior surface of the liver. He also mentions a case which

* Principles of Physiology, p. 197.

* Abernethy's Surgical Works, vol. I.

† Dr. Innes, Medical Communications.

‡ Howship, Practical Observation on Indigestion.

§ Monro, Morbid Anatomy of the Stomach and Gallies.

occurred to an Italian physician, where it depended on a worm in the cystic duct.

Mayo (*Outlines of Pathology*) mentions an instance of its occurring in a female, who was suffering from inflammation of the surface of the liver.

Stokes, in his *Clinical Lectures*,* mentions having met with it in several instances during an epidemic gastro-enteritis accompanied by hepatitis.

CASE. The Marquis of T.,† after suffering some time from disease of the liver, had an abscess in the right side, which burst, allowing the escape of pus and a great number of gall-stones. It then healed, but four other abscesses occurred in the next ten years. Six months before death, great difficulty in deglutition came on, for which leeches and blisters were applied, with but temporary relief. He at last sank from diarrhoea. The œsophagus was quite healthy, but the liver was reduced to half its usual size, and adhered to the diaphragm by cellular bands. The gall-bladder was wanting, its place being supplied by a little fibrous substance, in which ended the cystic duct.

STRICTURE FROM AFFECTIONS OF THE DIAPHRAGM AND THE PERICARDIUM. CASE. A female, aged 32,‡ began to suffer from difficulty in swallowing, with a constant sensation of constriction in the throat, and pain at the lower part of the sternum, accompanied by intense agony in laughing. The slightest sudden motion brought on an attack of the agony at the epigastrium. Warm baths, with opiate frictions and hemlock poultices, gave relief. She was ultimately cured by blisters to the epigastrium, and leeches to the anus.

Heister (*Obs. Med. Mis. Obs.* 15) reports an instance of a man suffering from inflammation of the diaphragm, who had spasmodic contraction.

In the following case, reported by Portal (*Mém. sur plus. Maladies*) the pericardium was affected. The mother of Dr. S. was taken with severe pain in the larynx and pharynx, affecting speech, respiration, and swallowing, particularly of fluids, which returned by the nostrils. Fever, with hard quick pulse, also existed. She sank on the seventh day. The larynx and œsophagus, to their great surprise, were quite healthy, but the pericardium was thickened of a dark violet hue, and adherent to the heart, which was also softened.

STRICTURE FROM AFFECTIONS OF THE UTERUS. Riedlin reports the case of a female who, at the fourth month of pregnancy, became subject to spasmodic contraction of the œsophagus, so that she was able to swallow only a little broth. Immediately after her confinement, it began to diminish, and at the end of a month she could swallow with the greatest ease.

In the *Ancien Journal*, the case of a woman is published, who suffered from this affection in eleven successive pregnancies. (*Leblond, Thèse de Paris*, 1822. No. 196.)

Villeneuve relates an instance of a female suffering from uterine disease, who had constant constriction of the throat. Pattissier at the same time mentions a like instance. A seton was introduced into the neck, but to no purpose. In neither of the cases was there hysteria.§

Mondiere|| met with it in a case of menorrhagia. In this case, it is doubtful whether it might not have depended on the loss of blood, and not on any uterine irritation. Sir B. Brodie, in his work on nervous affections, publishes the case of a lady who had suffered three years from spasmodic stricture, the result of repeated discharges of blood from piles. Her face was blanched, she could not swallow solids, and even fluids with much difficulty. A probang was passed with the greatest ease. By tonics and cold injections, she was, at the end of four months, able to swallow with ease.

Rechelmi¶ reports the following case. A F., aged 39, nervous, confined forty days. She had been much weakened by several causes, particularly by excessive menorrhagia. Soon after her labour, a sudden mental shock took away her

consciousness for some time. On recovery, she complained of painful constriction of the pharynx, food and liquid being immediately rejected. It was much worse during the day when up, particularly on walking, and was then attended with difficult respiration and palpitation of the heart. There was extreme emaciation. Great mental depression always preceded the dysphagia. Giving milk to the child always induced an attack. By cold bathing, and amusing her mind, she became, after suffering ten months from it, much better.

A young female,* brought up in the country, and accustomed to an active life, came to live in town to attend on an invalid. She first began to suffer from headache, loss of appetite, and constipation, followed by vomiting of all taken, and considerable emaciation. In a short time, she complained of pain in the throat, behind the cricoid cartilage; the attempt to swallow food produced constriction, followed by its immediate rejection. A common catheter was passed, with immediate relief to the dysphagia and vomiting. Medicines were given, but with little benefit to the hysteria and indigestion. The vomiting and dysphagia soon returned, although less severe. The catheter was again passed, with the same benefit as before. She was sent back into the country, and was soon quite well.

A chlorotic and hysterical female, aged 25,† in whom the menstrual discharge had been scanty for ten years, each epoch being attended with difficult breathing, during the last five years she had suffered from dysphagia. Food, when swallowed, was immediately rejected, and severe pain was excited throughout the whole length of the œsophagus. In the winter, the attacks would come on suddenly in the night, continue longer, and be more severe than at any other time; the tongue and uvula becoming affected, and at the same time frequent hiccough. Throughout the attack, a constant pain, of a spasmodic character, existed at the præcordia, which rendered the breathing difficult.

In the case published by Dr. Tilt, in his valuable work on *Diseases of Women*,‡ the person, aged 27, menstruated at thirteen, scantily and irregularly; at fourteen, it was attended with severe pain. She married at twenty-four, and had a child, which she could not suckle: the menstrual discharge reappeared at the end of three months. In the winter of 1851, she was taken with cough and pain in the pit of the stomach; and food seemed to meet with an obstruction just above the præcordia. She was awake on the fourth night of the attack, suffering from severe suffocative pain in the epigastrium. There was no fever. She had leucorrhœa, and the menstrual discharge was soon expected. The application of hot water gave relief. Sedatives were also given, and plasters of the same character applied to the epigastrium and the region of the ovaries. The pain, however, returned at intervals, rendering the frequent exhibition of morphia necessary. The menstrual discharge did not come on for three weeks. At the next period, she had colic, with pseudo-narcotism, followed by violent epigastric pain, which shifted to the spine, and passed down to the sacrum, then the menstrual discharge appeared. Since this time, she has been subject to spasmodic contraction of the œsophagus during meals. The food is suddenly arrested,—sometimes for a time only; at others, the whole dinner is brought up; but generally only the food, or a little ropy mucus,—after which she is enabled to eat a hearty meal.§

In the case published by Percival.|| A young lady, aged 13, had suffered, when seen, six weeks without any intermission from dysphagia. She had had dysphagia before, but it had left her for a month. Solids passed down to the orifice of the stomach, and were then rejected with a convulsive effort. Warm fluids, swallowed by sipping, met with no resistance; otherwise they were rejected. In the evening the spasm relaxed, leaving a sense of uneasiness at the pit of the

§ Dr. Tilt has had the kindness to inform me that she still continues in the same state.

|| Transactions of the College of Physic, vol. ii.

stomach. She had menstruated scantily at nine, but only twice since. Feet very cold, and bowels constipated. By the application of a galbanum plaster to the throat, milk diet, and exercise, cured.

Bright* mentions the case of a female brought into Guy's Hospital, suffering from stricture of several weeks' duration. The introduction of a probang brought on a fit of hysteria.

STRICTURE FROM GOUT. A case fell under my notice a short time back, where a person, while suffering from an attack of gouty spasm of the stomach, everything was rejected the moment it reached the lower part of the pharynx.

Mr. Watson (quoted by Howship) speaks of a case occurring in a gouty gentleman.

Courant describes a case where it preceded the paroxysm of gout.

STRICTURE FROM SUPPRESSION OF CUTANEOUS ERUPTIONS. Manclerc,† a case in a nervous female, where the suppression of an eruption on the back of the hand, by an astringent application, was followed by vomiting and spasmodic constriction of the throat.

Aird§ mentions the case of his son, aged 18, in whom the sudden disappearance of a chronic eruption was followed by swelling and pain in the umbilical and hypochondriac regions, and spasm of the œsophagus.

STRICTURE FROM AFFECTIONS OF THE MIND. An instance is recorded in one of the old writers, of a man who could not swallow a consecrated wafer. Another case is also mentioned, of a monk who never could swallow a particular kind of fluid, some of which had once found its way into the trachea.

Boyer mentions an instance of a female, who, having once had a piece of chicken arrested in the throat, never after could swallow any without its inducing spasm.

I am acquainted with an individual who cannot take a very small new potato, from a surfeit in early life. The moment one is introduced into the mouth, a sense of constriction is produced; and if he attempts to swallow it, it is rejected.

Percival relates an instance where swallowing a pea excited spasms of five or six days' duration in an elderly lady.

Duchateau (Tome 79 of *Jour. Gén. de Méd.*) has published the case of a nervous female, who fancied that she had swallowed a pin. She was at last cured by an enema, and then showing her a pin, telling her it had been discharged from the bowel.

Mondiere (*Arch. Gén. de Méd.* 1833) cites the following cases:

A man, the subject of hypochondriasis, after being bitten by a dog, took to his bed, and had difficulty in swallowing for fifteen days. But on Ferrier telling him that persons suffering from hydrophobia died on the eighth day, he got up and went about his usual occupations.

Barthelemi, the professor at Alfort, was bitten by a little dog. He believed that he was suffering from hydrophobia. For three days he was unable to swallow; the sight of water affecting him like electrical shocks.

Barbatini mentions an instance where a man, while out hunting, was bitten by his dog. The dog did not return home with him. Three days passed: the idea then took possession of him that he was hydrophobic. He had soon all the symptoms, even to occasional attacks of furor. On the ninth day the dog returned, well and playful. From that moment he became quite well.

A man had been absent from home for twenty years. On his return, he learnt that his brother had died of hydrophobia, from the bite of a dog which had also bitten himself. He was immediately seized with all the symptoms of the disease, and sank under it.

INFLAMMATION OF THE UPPER PART OF THE SPINAL CORD. Hoffman mentions an instance where spasm of the œsophagus existed in a case of inflammation of the upper part of the cord.

TURPENTINE IN THE TREATMENT OF PURPURA.

By WM. SMITH, Surgeon, Fellow of the Royal Medical and Chirurgical Society of London, etc.

IN the ASSOCIATION JOURNAL for June 27th, is a review of Dr. Neligan's work "On Diseases of the Skin"; and some remarks on the treatment of purpura by oil of turpentine.

Having recently had under my care two severe cases of this disease, and having treated each of them differently, I trust a comparative view of the remedial effects of the medicines employed will not be uninteresting. I must premise that my attention was drawn to the use of oil of turpentine by Dr. Copland's recommendation of it in the article on his disease in his Dictionary. The mode, however, in which I administered it, was advised by a gentleman of great practical experience in the treatment of disease, now retired from the profession, and who informed me that he had always found it successful in cases uncomplicated with organic disease.

The cases (which I purposely report very briefly), are as follows:—

E. W., aged 6, residing at Bolsover, Derbyshire, was attacked with large spots of purpura, principally on the lower extremities in the autumn of 1852. Her mother employed domestic and other remedies till the spring of 1853, when, the child becoming much worse, she called me in.

The patient was a very fine though somewhat plethoric child, with ruddy sanguine complexion, and with all the external appearances of rude health. The locality in which she resides is one of the highest and driest in England, and distinguished generally by the longevity of its inhabitants. About six-sevenths of the cases which fall under my care are, however, of the zymotic class. The drainage is bad, and many of the wells have been poisoned by the leakage of the cesspools. During the spring and summer of 1852, malignant scarlatina prevailed to an immense extent, and during this and last year furunculoid eruptions and erysipelas have been common and severe.

In the case now narrated, the child had for some time lived chiefly on animal food, in fact, on the usual farm house diet—bacon. On my first examination of her, March 15th, 1853, several very large ecchymoses were present on the legs, and one of the size of an egg on the forehead, the result of a slight blow. The smallest pressure produced them. There had been considerable bleeding from the nose on several occasions, and once from the bowels. There was oozing of blood from the gums. The urine was high coloured, and the alvine evacuations pale and generally constipated. I treated this case first with purgatives, and then with diluted sulphuric acid. She was also ordered to suck oranges, drink lemonade or very weak beer, and to eat rhubarb tarts.

The case did not progress with this treatment; the epistaxis was, indeed, somewhat diminished, but the other symptoms continued much the same.

Under these circumstances I gave the child citrate of iron combined with citric acid. This succeeded better, and after three months perseverance, the cutaneous discolorations ceased. The progress of cure was, however, extremely slow, and a relapse has since occurred, but the patient has again recovered under the use of the citrate of iron.

The second case occurred in a little girl, aged 4, generally strong and active, and residing in a spacious house situated near a tannery. This case was very acute. There was first remarked in her a disinclination to food, especially vegetable; and extreme irritability of temper. The bowels were extremely constipated. These symptoms ushered in the attack. The lower extremities became weary and stiff towards evening, and three large elevated spots, varying from the size of a fourpenny piece to that of half-a-crown, appeared upon them. These spots became rapidly purple and soft, and gave the impression to the touch of fluid blood under the skin. In the morning they became yellow, and gradually were absorbed, but others, larger and higher up

the legs succeeded. Two formed of a very large size in the hams, and the skin became so thin that I thought it would give way. The child, in three days, became pallid and exsanguine, and her pulse very sharp and hæmorrhagic. After using a mercurial purge, I at once resorted to the following mixture.

Rx Olei terebinth. ʒss.
Olei ricini ʒj.
Mucilaginis,
Sacchari, aa, q. s.
Olei caryophyl. gtts. iv.
Aque dist. ad ʒviij.

Misce ut fiat mistura, cujus sumat cochlearia ij. vel iij. bis vel ter in die.

The effect of this mixture was most satisfactory. The purpuric spots rapidly disappeared, the bowels acted copiously and naturally, the appetite of the child became good, and the temper cheerful.

I certainly believe that in all passive hæmorrhages, turpentine will be found most valuable in its effects; and in this class of diseases we must generally place purpura.

Chesterfield, August 20th, 1853.

GALLIC ACID IN THE TREATMENT OF PURPURA HÆMORRHAGICA.

By T. P. J. GRANTHAM, Esq.

SOME years ago I lost one very dear to me from purpura hæmorrhagica; and my attention was thereby strongly directed to that disease, with the hope of discovering some more satisfactory mode of treatment.

The value of gallic acid in passive hæmorrhages induced me to give it a trial in purpura hæmorrhagica, and the results obtained were very gratifying. Moreover, its safety, promptness, and pleasantness, are no inconsiderable recommendations of this remedy.

If the reader should not find any novelty in the application of gallic acid to this disease, the subjoined cases will at least confirm, as far as they go, the value of the treatment.

CASE I. Mr. E., a farmer and miller, aged 60 years, came under treatment on the 18th November 1852. Two days previously, he had noticed a soreness of the tongue, and perceived that the saliva was bloody. The symptoms of purpura were well marked. The gums were spongy, and they bled freely. The tongue and the buccal mucous membrane were dotted with purple fungoid excrescences, some of which were as large as split peas, and from them blood oozed. The breath was offensive, and the appetite was impaired. The urine contained a considerable quantity of blood. Petechiæ were scattered over the thoracic and dorsal regions; and there was a large ecchymosis on one arm, and another on one of the thighs. The gallic acid was administered in five grain doses every three hours, and two compound rhubarb pills were given at bedtime. On the 20th, the purple excrescences had shrunk and ceased to bleed; the petechiæ and ecchymoses had faded; and the urine was free from blood. On the 30th, the improvement had been sustained. He was quite well again. He said that the first dose of medicine seemed to do him good. Only four scruples were taken.

CASE II. This was a more serious case, several days having elapsed from the first setting in of hæmorrhage from the nose before the patient came under my care. Master C., aged 16 years, a draper's apprentice, was seen by me on the 21st June 1853. He was greatly exhausted and blanched from epistaxis, hæmoptysis, mælena, hæmaturia, petechiæ, and ecchymoses. He was immediately ordered to take gallic acid in doses of three grains every three hours, and subsequently in five grain doses every two hours. The pil. rhei comp. was given as an aperient. The treatment was followed by most marked benefit, and before a week had elapsed, all hæmorrhage had ceased. On the 5th July, a slight recurrence of epistaxis happened,

owing to his having too soon resumed active exercise. But the bleeding was quickly checked by a few doses of the acid, and complete convalescence speedily followed.

CASE III. H. B., aged 12 years, son of an agricultural labourer, after three weeks illness from typhus, then prevalent in the village where he resided, was seized on the 16th August 1853, with hæmorrhage from the nose, gums, and bowels. The tongue was dotted with purple spots, and the back sprinkled with numerous small petechiæ. The treatment adopted was the same as in the former cases. On the 17th, hæmaturia was superadded to the other symptoms, which were very severe. On the 18th, the hæmorrhages began to abate. On the 20th, the spots on the tongue and the petechiæ had faded; the hæmorrhages had nearly stayed. On the 21st, a severe return of epistaxis occurred, from picking his nose. This was followed by alarming prostration of strength. He was ordered to take the acid every hour, and to have his nose plugged. On the 22nd, all bleeding had ceased. On the 30th, I found that there had been steady and daily improvement since last report. On the 31st, he was convalescent.

This was a severe case, as the patient's strength had been so much reduced by a previous exhausting disease; and, accordingly, it was necessary to push the acid to a considerable extent.

In all the cases the dietetic and general management were carefully attended to.

Burgh-le-Marsh, Lincolnshire, Sept. 1st, 1853.

ON FEVER IN RURAL DISTRICTS.

By W. VINER BEADLE, M.D.

IN recent numbers of the ASSOCIATION JOURNAL, I find reports of discussions at the Epidemiological Society, on different kinds of fevers. On a subject of such importance I venture to break the seal of silence, the "*sigilla grata pudico*", and to offer the following remarks on the Fevers of Rural Districts, as I have myself observed them.

My own impression is, that all the *true fevers* are closely connected with one another in origin and nature; that certain endemic even more than epidemic causes may produce these; but that, once brought into existence, they may under certain circumstances, only moderately favourable, be propagated; but that, these favouring circumstances being removed, they sink for want of their proper pabulum.

I, therefore, fully agree with the remarks of Dr. Southwood Smith, that "fever is no doubt capable of extinction. The old fevers are now unknown; and were the earth cultivated like a garden, and the people all rational beings, it would soon cease." New modified forms, it is true, may arise of the same type, and yet bear no further comparison than does our present newt to the ichthyosaurus of geologists.

On looking at the number of deaths by typhus in the Registrar-General's report for 1842, I find it to be 16,201, of which a large proportion occurred in country districts. It is to this latter class that I now more especially refer.

Amongst the circumstances which I recognise as the most favourable to the development of typhus fever, are—

1st. The *nouveau séjour* of Broussais, in places where the resident inhabitants are little affected.

2nd. (a) The want of drainage and ventilation; (b) human effluvia concentrated; (c) damp and consequently a cold and depressing neighbourhood and soil.

3rd. Though in a less degree, infection from those already affected, if *also* exposed to the same polluting influences.

Such is my impression of the origin of our fevers; and such causes must be efficiently removed ere fevers will vanish. I do not mean to speak dogmatically, since I am happy to say that my experience is comparatively limited; though even the cause of that limitation is not without a bearing on the subject. "Many years ago," remarked a gentleman to me, "fever always raged here towards the autumn; and many who were able felt great anxiety to escape at that time from the town." Now, however, since

drainage and cleanliness have been more attended to, matters have been very different.

I have often heard it remarked, that were fever capable of arising from purely local, i.e., endemic causes, it could not occur on a hilly locality, since drainage and dryness must necessarily be there. The latter, at least, was not the case in two recent instances:

1st. In a set of houses of dubious ownership and neglected state.

2nd. In another hill, a fine, open, country spot, where fever was rapidly spreading through a row of houses, when, on adopting my usual practice to inspect the drainage, I discovered the cesspool of the privy quite full and extending beneath the sitting room of the house where it commenced. Of course, its instant removal was resolved on. No fatal case occurred; and since then there have been no fresh cases.

I have found fever of adynamic character occurring in the house where I first met the collapsed stage of Asiatic cholera: in a low, damp spot, where the Chell, reeking with the filth of the town standing on it, added its baneful exhalations to the other causes.

I have seen fever in the small and low farm house, pent in by abominations. I have seen it in the butcher's house, his lower rooms reeking ankle-deep with the filth of the slaughter house. I have seen it in the cottage of the poor, with its atmosphere saturated with human pollution. I have seen it breaking out under exciting causes amongst the newly arrived, whilst those accustomed to the place withstood its baneful influences. I have seen it on the swampy banks of the Thames, Severn, and Somersetshire Avon, when neglect or want has added to the unfavourable circumstances of the case. *But I have never seen adynamic fever arise in any place where neglect had not produced malarious influence, and where more or less of exhaustion, and privation, or want and misery had not induced it.*

But, though so much has been said of the fevers of large towns, so little has been said of it in country districts, in hamlets, or villages, that the subject has been almost overlooked. "Rusticus expectat" is the old adage; and hence it is the more important for those who can observe to call to action. Celsus, indeed, quotes a saying of Asclepiades; "Asclepiades officium esse medici dixit, ut tutò, ut celeriter, ut jucundè curet". But the modern physician recognises a further duty; viz., to observe and bring his knowledge of the laws of nature to bear where it is required—not merely to cure but to prevent.

The question is not now to discuss simply whether anything or what could have saved some or other case when actually attacked. It is this: Can the cause of the whole be removed? We cannot, indeed, root out a law of nature; but we can so modify these laws that she shall yield the golden grain instead of the worthless weed.

A series of cases of fever having occurred in the hamlet of E., small in actual number, yet large as compared with the very scanty population of the place, may serve to show that the causes I have mentioned and the fever were at least coexistent.

CASE I. November 1852. John G., aged 7, was seized with mild typhus fever; but in about seven days it had so far subsided as to leave him in a state of approaching convalescence. After this, several slight cases occurred in the neighbourhood.

CASE II. February 8th. Ann G., aged 34, required attendance. She was then suffering from bronchial irritation, and it had much the appearance of a cold or influenza, save that she complained of more lassitude, feebleness and want of sleep. She had a rather quickened pulse (90).

For a few days, under the rest and the treatment adopted, she seemed to improve, though much was unfavourable to this. Seven persons slept in one small room; and the husband's earnings, though a strong young man, only amounted to 7s. per week.

February 24th. She still coughed a good deal, with a white frothy expectoration. The pulse was 90; the respirations 30; the skin hot and dry; the tongue dry; and she complained of heats and chills, with severe aching about the

limbs. The hearing was impeded; and there was general dejection of mind. The respiration was short and anxious; the skin dry and hot; the breath was offensive; and accumulation of sordes was commencing on the teeth; stupor was present, requiring her to be roused. All showed, in the absence of sound sleep, the approach of adynamic fever. The treatment adopted was gentle diaphoretic anodynes for the cough; a simple saline mixture every four hours; and a little wine in water arrowroot.

February 26th. The pulse was 120; the bowels had been moved five or six times a day. Submucous crepitation (loud mucous rhonchus) was heard all over the chest; and she expectorated white frothy mucus. In other respects she was as at the last report. The following medicines were prescribed.

Rx Pulveris ipecacuanhæ comp. gr. iv.
Camphoræ gr. i. M.

Fiat pilula urgente diarrhœa sumenda.

Rx Decocti cinchonæ flavæ Oss.
Liquor. ammon. acetat. concent. 3iv. M.

Sumat cochlearia ij 4tâ quaque horâ.

March 1st. The pulse was 120; the respirations 50. She seemed now to doze a good deal by night and day. The cough was less troublesome. She had dulness of hearing; and there had been continual wandering and muttering day and night for the last two days. She complained of no pain. The bowels were now open only twice a day; but the motions were passed almost unconsciously. She had the indescribable stupid look of adynamic fever—"Defixis oculis, animoque et corpore torpet."

She remained much in the same state, save that the general exhaustion of mind and body increased, with picking at the bedclothes, sweats about the breast and head, hiccup, more quickened and feeble pulse: and the peculiar listless expression of countenance increased, until life can hardly be said to have remained. March 15th, she died.

CASE III. Occurring at the same time, I had the case of her daughter, Mary G., aged 15.

February 24th. This day I found her suffering from symptoms of fever, though still nursing her mother's infant. The disease commenced precisely as her mother's, with weariness and bronchial cough. On being questioned, she said she felt ill; and looked most exhausted and wretched.

February 26th. The pulse was 120; the respiration 30. She was very thirsty. The tongue was becoming dry with red edges. The bowels were purged five or six times in the day and night; but she said she had no pain. The cough was troublesome; the expectoration scanty, white and frothy. The skin was dry and rather hot. Simple mild salines, with hyoscyamus and mild opiates for the diarrhœa and cough, were ordered.

March 6th. The pulse was 120, tremulous; the respiration 40. The bowels were moved five or six times a day. The head was hot; the tongue dry; the urine moderate. The abdomen, on firm pressure, was tender and rather tense.

March 8th. The respirations were 44; the pulse 112; the tongue moister; the skin dry. She did not cough so much. The tympanitis of the bowels had now become excessive. Fomentations and terebinthinate embrocations were employed; and a tube was passed *per anum*. The urine was moderate in quantity. Her motions were passed under her, partly from unconsciousness, partly from debility. Wine, arrowroot, and bark, were ordered.

I had here to contend with great inefficiency of the nurse, as she remained only during the day, leaving the sick at night almost unattended.

This case proceeded much as the last until the 12th, when with stupor, delirium, and relaxed sphincters, she died.

CASES IV and V. I have the history of two other cases, which were proceeding during a part of the above period, and occurred in a parish near the above. The individuals had come to reside "very recently" there; and each of themselves, none were affected.

They both commenced with hepatic derangement, recovering in a few days. In the other, the

gressed over the abdomen. The debility and the peculiar look of stupor increased.

On February 11th, the third day from my first seeing her, she complained of soreness and aching all over. The bowels were still rather painful, but less so. She had pain of head, languor, and lassitude, which she described as having come on gradually, accompanied by alternate chilliness and flushing. The respiration was rather short and anxious; the pulse 100, frequent, weak, and intermitting. The tongue, at first moist and slimy, was now dry and rather brown, but moistened on taking water.

February 14th. The tongue was dry and rough. Her countenance had an anxious, trembling appearance; and there was a good deal of muttering stupor. She wandered and dozed at night.

This case was much marked by imperfect crises, and an improvement would take place, to be followed by increase of the symptoms on the following day.

She continued, with gradually moderating symptoms, until March 8th, when convalescence was so far set in as to admit of her removal to her mother's. She soon finally recovered.

CASE VI. The next case that came under my notice was that of Anna T., aged 65, a relative of the G.'s, who had nursed them by day; but by night were left almost entirely to themselves, save such assistance as the wearied husband could give.

I was called to her a few days after her daughter's death on March 23rd. She was then suffering from lassitude, pain of the head, rigors and flushes, aching of the limbs, and want of sleep. Before the attack was developed, she had removed to another and distant house. In about ten days, the symptoms had so far abated, that convalescence had well commenced, which was aided by wine and bark.

CASE VII. April 16th. On further proceeding, I find the case of Anna B., aged 60. This case was comparatively mild in its character. There was no abdominal, and only slight bronchial complications; and, in about ten days, convalescence had set in.

CASE VIII. April 27th. I was sent for to Harriet P. She had at different times been attending on those suffering from fever, and for the last fortnight had been very unwell, though still getting about a little. For the last two days, she had felt languor and lassitude, with alternate flushings and chills. She could not rise up, from giddiness and feebleness. The pain of the head was severe; she "maundered" a good deal, but could not sleep at night. There was tenderness at the epigastrium and the right hypochondrium. The pulse was 110. She had a trying bronchial cough.

May 2nd. She was in some respects improved; still, however, she did not sleep at night, and had not for many nights past. If she dozed, she says, "for a bit", she woke up, and her head began to wander; but it wandered last night less. The pulse was 110. As her tongue was less dry, and also the skin, I now ordered her wine and bark, etc.

May 11th. The pulse was 90; the tongue clean. She slept moderately well. She was considered convalescent, except that she was very feeble both in body and mind.

CASE IX. April 30th. Susan B., aged 70, had been ill a few days. The pulse was 100 while lying down. She had had great sense of feebleness and exhaustion, pains of the limbs with aching, inability to sleep at night, and "wandering of the head". On dropping off to sleep at night, her head wandered, and she began talking. Her skin was hot, and rather dry; the tongue moderate, but coated; and she had troublesome bronchial irritation.

This case followed a medium course, and by the 10th she was convalescent.

CASE X. May 13th. Anne S. This case was of a mild character, and convalescence commenced in about a week. It offered no severe complications.

CASE XI. June 5th. George Y., aged 50, came under my care. He was of a feeble habit. He had been recently

reduced in circumstances to the rank of a labourer, and was much depressed in mind.

I had accidentally seen him a few days before, when he was suffering from diarrhoea, with a coated tongue, and some slight soreness over the umbilicus and abdomen. I prescribed a few doses of hydrargyrum cum creta, and compound soap pills, with camphor, for the diarrhoea. Under this, he improved in that respect.

June 10th. The disease now assumed the form of fever. He had been wandering all night, though perfectly sensible on being roused; but would relapse almost immediately. He lay on his back, and did not complain of pain. The signs of exhaustion were very evident in his face and movements. The tongue was red (scarlet) and dry; the skin hot, but clammy; the pulse 80. He had been delirious at intervals for the last two or three days. The head, however, was not hot. The urine was moderate. He had had offensive motions on the previous day. His memory quite failed. Wine and arrow-root were given, and decoction of bark, with acetate of ammonia; also four grains of hydrargyrum cum creta at bed time. Chalk mixture with opium and catechu was prescribed for the diarrhoea. Turpentine and opium embrocations were applied over the abdomen.

June 14th. The pulse was 88; the tongue red and dry. He dozed off at intervals, and, on waking up, wandered. The skin was hot, the head cool, the face flushed. There was some tenderness in the abdomen, but no tympanitis. He had five motions on the previous day. He talked sensibly at intervals. He sighed often, and lay on his back. He was not very thirsty, but occasionally called for toast and water. Hiccup was now come on.

June 19th. Pulse 80. He was purged three or four times yesterday, and twice in the night. The tongue was red, and dry, if not moistened. The eyes were half closed, showing the lower part of the albuginea. He dozed and wandered, but, when roused, he answered rationally. The bark and ammonia were repeated.

R Pulveris ipecac. comp.,
Extracti hyoscyami, aa gr. ij.
Camphore gr. ss. M.

Fiat pilula urgente diarrhoea sumenda.

The turpentine embrocations to the abdomen were continued; wine and arrow root were ordered.

June 24th. He remained much in the same state, with dorsal decubitus. Subsultus tendinum and hiccup were nearly constant. His urine and motions were often passed unconsciously. There was evidently tenderness at the lower part of the abdomen; but his want of sensibility to external impressions rendered it difficult to determine.

June 29th. Pulse 100. He was more exhausted. His mind dwelt, as it had all along, on his change of circumstances. He had never felt the slightest care as to recovery or death. Hiccup and subsultus continued, and he fancied he saw something behind the curtain—the result evidently of the delirium of exhaustion.

July 7th. He died this day.

I now come to the last case of the series.

CASE XII. Anne P., aged 23, was a young person of moderate health, and had a child six months old at the breast. She had for a few days assisted in nursing the previous case.

June 22nd. She was in bed. The pulse was 110; the tongue white, and much coated. She had not felt well for a week, but had been low and depressed in mind, with aching of the head, back, and limbs, and weariness, chills, and flushes. On the preceding evening, she had been sick, and had vomited green fluid. The skin was moist, the head cool, the state of urine and bowels moderate. The head was very painful. The following medicine was prescribed:

R Hydrargyri cum creta gr. iv.
Pulveri antim. com. gr. i. M.

Fiat pulvis 6tis horis sumendus. Mitte iv.

A saline mixture was given every four hours.

June 25th. The pulse was 100; the tongue more coated, but moist; the head hotter, but less painful. During the

night, she had been wandering and dozing. She was more thirsty. The skin was hot, but not burning; the pupils were rather dilated. The bowels and urine were moderate. Her countenance had now assumed the stupified look of fever.

June 30th. The pulse was 90. She slept moderately, and the tongue was cleaner. She dozed at intervals for a short time, but, on waking up, her head seemed to wander. The improvement in the pulse, tongue, and sleep, with the moist skin, and the wandering of exhaustion on waking up, showed the time for the exhibition of wine and tonics; but her age and constitution warranted in delaying them until now.

July 6th. She was improved, and able to sit up a little, though still very exhausted and feeble. The child had been weaned at first.

The above extracts refer to the history of the cases. Their peculiar complications appear to have been modified by season and atmospheric causes. Thus the two G.s had severe bronchial complication from the very first; bronchitis and colds being very prevalent at that time. The enteric mucous membranes, however, soon became affected; and, in the case of the younger one, death followed the accession of tympanitis. Cases vii, viii, and ix, began also in the same manner. Cerebral affections supervened. In the two cases I refer to as instances of "*nouveau séjour*", fever was ushered in by hepatic disturbances, and the abdominal mucous membranes did not become prominently affected. In the case of George Y. (No. xi), the constitution of the season had by this time changed, and irritation of the abdominal mucous membranes, ushered in by diarrhoea, continued more or less throughout. In the case of Anne P. (No. xii), the cerebral implications were most manifest.

The treatment was adapted as far as possible to the circumstances. The bronchial complications were treated with diaphoretics and mild anodynes, combined, if commencing early, with a slight nauseant; the diarrhoea, by a smooth farinaceous diet, Dover's powder, and camphor, with small occasional doses of hydrargyrum cum creta, and especially external rubefacients. Wine, bark, etc., were given according to the strength and stage.

Thus far had the cases proceeded, when I called attention to the state of the place; for the occurrence of ten cases of fever in a population of fifty or sixty persons demanded inquiry.

On June 25th, in company with the Rev. —, a neighbouring clergyman, and Mr. —, I visited several parts of E., with a view to examine the state of the drainage, general cleanliness, and sanitary appliances of the place.

1st. We examined the cottages opposite the house of Mr. J. Y. Opposite to them, in front of Mr. J. Y.'s house, was a large dung heap, in course of turning or removal. On one side was a pool of stagnant water; near it a heap of filth, flung out from the different houses in front of the dwelling; and, at a short distance, a privy, draining its contents into a ditch, and carried off as the rain might avail.

2nd. We examined the houses called H—'s houses. These are six or eight in number, solidly built, having formerly been barns, but utterly destitute of proper drainage. One row of them seemed to be worse than the other. Stables and pigsties surrounded them; and close by, the *cabinet d'aisance*, a miserable place, visible to all, without a door, and unclosed, protruded its contents into the open air. The women, being unable to go there for want of privacy, made use of utensils up stairs, and emptied these into the open gutters, which slowly dribbled it into a shallow ditch.

One of the inhabitants, a woman, described the stench in the morning as being "dreadful". She would not stay there, but could not help herself. The water in the well was brackish.

The other row was much in the same state. The ordure from all these houses, in which about forty persons reside, was discharged in the midst of them all; to say nothing of pigs and horses. No under drainage whatever seemed provided. Three cases of fever occurred here in one house; the nurse also had an attack.

3rd. We examined the farm house belonging to Mr. —, and recently his residence. A ditch close behind the house, reeking with filth, first attracted notice. Into this the general refuse of the house was discharged, and left to escape or putrify as it best might. The *cabinet d'aisance* was in a bad condition, open and foetid. In front of the house was the cattle yard, in a state of sad neglect, with an overwhelming stench; and there was a deep bricked pit, intended to hold the pigwash, filled with a foetid fluid, loaded with animalculæ and insects, and giving out bubbles of gas. These altogether shewed a state of things in the highest degree detrimental, and induced the Rev. — to exclaim that it "breathed out typhus". The entire place appeared the seat of ignorance, neglect, ruin, and filth, though belonging to the chief proprietor. The back of this place nearly adjoined the last named row of houses. This house was much surrounded with trees, which, preventing a free current of air, greatly increased the malarious effect.

4th. We next examined the houses occupied by —. They presented a ruinous condition. A large stagnant pool was in front. The necessary conveniences were in a bad state; and heaps of filth and household refuse lay near the doors. One case of fever occurred here.

5th. The next place examined was a row of cottages near Mr. —'s, belonging to Mr. —, as I was informed. They were low thatched cottages. In one of them fever was then present. One privy served them all; and this was quite open and offensive. The ditch into which it drained was choked up, and the contents regurgitated into some of the houses, producing a disgusting stench. The whole was closed up by trees, which of course prevented a free supply of air, and increased the mischief.

The hamlet, though large, consisting of some thousand acres, has yet but very few inhabitants; and the above description refers only to those places where fever actually occurred. I have referred to them only to take cause and effect together. In some parts they were much worse. These lay in the main or central parts of the place; and, though a few new cottages had been erected, yet many of the remainder consisted of merely one-roomed mud cabins, like those of squatters, seated in a wild uncultivated part, called the "Furzens", and having no available road, were almost unknown.

But the cause of this waste of life and land, lies perhaps still deeper. The tenure of the property is for the most part lifehold, held under ecclesiastical corporations. The consequence is, that no one having a direct interest in its improvement, it remains much as it was centuries ago: whilst some of the farms have so often injured their occupants, that even now they lie unlet. Some of the adjoining parishes, where the tenure is different, present a contrast. There all looks improvement; here decay. There the proprietors reside and the tenants live; here the real proprietors care neither for flock nor fleece; the semi-proprietors fly off daunted from the spot; the tenants, with large, though low-rented farms, are often unsuccessful; and the *adscriptæ glebæ* pine on the humblest wages, or die of fever.

The soil is very stiff and retentive of moisture, being for the most part unenclosed; the ditches even are few; therefore the many hundreds of thousands of gallons of water which annually fall on each acre, are mainly carried off by the surface. The atmosphere being thus loaded with moisture, has a temperature perceptibly lower than that of the surrounding districts.

Excessive dampness of the soil is therefore evidently one great cause of disease. It is pitiable to see the water standing in the furrows during the rainy season, without a hope of escape; to see the mountainous looking ridges with their tops peering up between, or the little starvelings of corn growing on their lower sides, as though bounteous nature was here rearing stepsons. But worst of all is it to see the roads in such a district. The main one is bad to the extreme; the off ones are not in existence, but the waggon horse follows his perilous track, floundering to his knees in mud or ruts, perhaps for miles, like a ship in a storm.

It is of no use to talk with those who contrive to exist under such circumstances. "Us lives as long as our neighbours, and we pays our way; and I don't see any use in what you talk of," was the reply of one magnate to my remarks, though severe disease was so prevalent in his community. But I submit it to the judgment of the profession, whether there is not a close connexion between the two states? Is there no connexion between such tenures and such a state of things, that whilst much around is flourishing, here is neglect or decay; and that within sight of, and only a few bowshots distant from, one of our towns of luxury and ease, and whose practitioners boast of their ignorance of fever?

I should much like to know the experience of others, as to the state of parishes under such tenure; since, if such are its effects elsewhere, it is high time that its days were numbered. And it is no more political to discuss such questions, than it is polemical to investigate the educational neglect of such and similar localities.

There doubtless is a connexion, since pathology points out that derangement of function always results from some change, either in the structure or composition of the tissue itself, or from some corresponding vitiation in its proper stimuli. Under such conditions, the vital tonic of all is diminished, and the typhoid ferment soon vitiates the fluids.

The place lies on the *lias*, consisting of *lias* proper, blue marl, and clay. Under this lies the saliniferous marl of the new red sandstone formations, and which crop up at not distant places. The saliniferous current seemingly takes a southern direction, passing through Droitwich, Tewkesbury, Cheltenham, Stroud, etc.; at all which places saliniferous springs are to be found, occasionally impregnated with sulphur.

It is a good dark and deep soil of vegetable mould, mingled with the decomposed *lias*, and capable of high cultivation; but it is evident, from the nature of its underlying formations, that deep and thorough drainage is the only way to render it available for agriculture, or properly habitable for man.

But I fear that, generally, the condition of the rural population will not bear inspection; and that our rank as a nation in the social scale must suffer, if means are not taken for its improvement. Unfortunately, however, enlightenment has only to a very limited extent pervaded the agricultural mind; and its *Epicuri de grege porci* still slumber on.

Tewkesbury, Gloucestershire, August 25th, 1853.

ON THE TREATMENT OF CHRONIC AND OTHER DISEASES BY BATHS OF COMPRESSED AIR.

By THOMAS POYSER, Esq., F.R.C.S.Eng.

As I am not aware that the treatment of diseases by baths of compressed air, now practised so extensively and successfully at Lyons, has been described in this or the other medical journals, a short account of it may not be unacceptable. Under this impression, I subjoin a translation I have made of a small tract, recently published by Dr. Milliet (descriptive of the method of constructing and using these baths), which was placed in my hands a week or two ago, by Dr. Strange, of Naples. This gentleman, who is now in this country, visited Lyons on his way, and made particular inquiries of the medical practitioners there, as to the extent to which this treatment is carried, and the success attending it.

The result of Dr. Strange's investigation led him to form a very high opinion of the great advantages of this practice, in the management of many obstinate and intractable diseases. From his testimony, and from a communication with which I have been favoured by Dr. Petrequin, I am induced to think that it merits the attention of medical men

in this country. Dr. Pétrequin was for many years principal surgeon to the Hôtel Dieu of Lyons, and is now in extensive practice in that city. He is also favourably known by his researches on the salts of manganese in combination with steel; and by his introduction of these valuable remedies into medical practice.

Dr. Pétrequin has no interest whatever in these baths: that is, he is neither the inventor, nor does he derive any emolument from them; but he has frequently witnessed their effects, and the following short statement is chiefly the result of his own experience. He believes that the bath acts on the system in two ways: 1. By its mechanical pressure. 2. Chemically, by infusing into the system, *i. e.* the blood, a larger quantity of oxygen than it would otherwise receive.

1. The effect of pressure on the surface of the body is, to drive the blood into the interior parts, and thereby give the vessels time to recover their tone: in this way inflammatory eruptions of the skin, and ophthalmia, are relieved or removed. Dr. P. has seen patients go into the bath with the conjunctiva quite red, and in a short time come out perfectly pale. He does not state that this effect is always permanent; but, by repeating the process, time is given for the vessels to recover themselves, and the disease is effectually removed. Again, pressure acts on the absorbent system in a remarkable manner, as is frequently witnessed in the absorption of external tumours; but it is only by means of the air-bath that this pressure can be applied to the lungs and air-tubes. Dr. Pétrequin believes that by means of this bath, we can cause absorption of the lymph or mucus which is effused in cases of bronchitis, either on the surface of the mucous membrane, or between this and the lungs; and which thereby prevents the entrance of oxygen into the blood. Dr. Pétrequin goes so far as to assert, that this pressure will cause the absorption of tuberculous deposits in the air-cells; but he does not state that he has witnessed any positive proof of this having been accomplished.

2. Dr. Pétrequin believes that the bath acts favourably in many diseases on chemical principles, by infusing a larger quantity of oxygen into the blood than it would otherwise receive. The fall of the pulse, and the diminution in the number of respirations, soon after entering the bath, are remarkable proofs of the correctness of this theory: for if at each inspiration a third more of atmospheric air can be introduced into the lungs, it is clear that the inspirations may be diminished by one third, and the same quantity of air be still received. As the number of pulsations bears in general a certain proportion to the number of respirations (say about four to one), it is evident that, as these diminish in frequency, the pulsations will do the same.

M. Pétrequin has seen the pulse fall in a short time from 120 to 80, or less. On these two principles of mechanical pressure and increased supply of oxygen, the compressed air-bath has been used with advantage in asthma, humid or spasmodic, but more particularly in the former; in emphysema, and various other chronic affections of the lungs and air-passages; in deafness dependent on thickening of the membrane of the ear: in various affections of the uterine system, amenorrhœa, chlorosis, chronic inflammations, etc., etc.; in enlargement of the liver and spleen, and other visceral diseases; also in dyspepsia, hypochondriasis, and in almost every kind of chronic disease.

Having made this short statement of the high estimation in which these baths are held by eminent and disinterested physicians who have witnessed their effects, I now proceed to give the proprietor's account of the method of constructing and using them.

THE MEDICO-PNEUMATIC ESTABLISHMENT OF AIR-BATHS AT LYONS. BY DR. MILLIET.

This establishment, which I opened at Lyons last year, was erected under the direction and advice of the inventor himself, M. Tabarié. I thought I could not do better than to act up to his principles, his process, and method.

The physical phenomenon which characterises this process is the augmentation of atmospheric pressure, and de-

depends on that property of the air, its *compressibility*; hence it results that in pumping the air in, we can retain in the same space a quantity infinitely greater than in the ordinary state. It is this which happens in the air-bath. To a volume of the confined atmosphere, which cannot vary, we increase successively the quantity of air which it contains; the retained air tries to escape, and then this pressure acts on a double glass tube, in the form of V, half filled with mercury; and influences, from its force, the ascent in the mercury in the opposite branch. This mercurial tube is the guide and test of the pressure, *i. e.*, of the quantity of air contained in a given volume; it is, in fact, the manometer.

The air that is collected in this apparatus is the ordinary atmospheric air; it undergoes no change; its temperature is that of the external air in temperate seasons of the year; but in extreme seasons it is cooled or warmed, in such manner that the patient neither experiences the sensation of heat nor cold.

The apparatuses are hollow spheroids of wrought iron, of various sizes. I have had three constructed of different dimensions. Two are intended to contain one person, or two at the most. They are about five feet in diameter, and ten high. The third is a collective apparatus, which will contain ten or twelve persons at a time. It is about ten feet in diameter, and has a vestibule or porch, by which any one may enter or leave it, without disturbing the progress of the operation. In the small apparatus, light is admitted by an opening about thirty-three inches long and eighteen wide. The collective apparatus is lighted by four windows, of about five feet high and one and a half wide. The doors of the small apparatus are about five feet high and two wide, and are made of wrought iron; and so thick as to resist a pressure two or three times greater than the maximum one. The doors of the large apparatus are of cast iron, about an inch thick. Their dimensions are, in height about six feet, and in width two and a half. The interior of these apparatuses is lined with silk, to prevent the disagreeable contact of the iron. The inferior segment of the spheroid is carpeted, and the whole has the appearance and comfort of a parlour. The air is pumped in through a tube placed under the carpet, and in the centre of the upper dome, is placed a tube for the escape of the excess of air, and of that vitiated by respiration. The pumps have a diameter sufficient to furnish hourly in the small apparatus 45,000 litres (upwards of 10,000 gallons) of air. In the large apparatus there is the same disposal of the conduits; but the pump which supplies it furnishes a greatly increased quantity of air, and consequently gives an enormous renewal of it. The pumps are worked by steam engines, one of three horse power, the other of ten. The mercurial manometer regulates and directs the pressure. The least pressure that I employ is about fourteen inches of a column of mercury, or nearly half an atmosphere. The greatest pressure is about twenty inches, or two-thirds of an atmosphere. The duration of each sitting or bath is two hours.

The first half hour is occupied in raising the pressure to the desired height; the next hour, the pressure is continued the same; and the last half hour is employed in reducing it to its ordinary state. This slowness in the transitions is the fundamental law in the air-bath: unless the change or transition be well regulated, the air-bath will do harm instead of good. It is certain that, if this law had been known in the submarine excursions with the diving-bell, many of the injuries from it would have been avoided.

During the whole sitting, an assistant directs the elevation, duration, and decline of the pressure. He does not quit his post for an instant; so that the patient may obtain from him, at any moment, any assistance or change he may require.

The air-pumps and engines are superintended and directed by any engineer during the whole time they are employed. The patient, while in the bath, can read or talk at his ease; and, with the exception of a slight pressure on the ears (a sensation which usually goes off on swallowing a little of the saliva), experiences no feeling which can

make him think he is not in, and breathing the ordinary atmospheric air.

These structures or baths, to which we have given the name of "bells", from their resemblance to the diving-bell, are placed in two elegant cases, separated from each other by a small entrance hall. From the interior of the apparatus, the view extends over the plains of Dauphiny, between the Rhone and the Alps. A library and the journals are at the disposal of patients who use these baths.

It is in affections of the organs of respiration, and of the circulation, that the compressed air-baths exert their special influence, and effect a new and peculiar mode of treatment. I do not intend here to show or trace the extent of their influence, leaving that to experience, which can alone settle it. I can, however, say with truth, that, in all the chronic diseases of respiration which I have treated, my success has exceeded my expectation. In fact, we may conceive that, in diseases of the lungs, its action is direct, whether the compressed air act by assisting sanguification, or by regulating and harmonizing the circulation. One of the most remarkable phenomena occasioned by the increase of atmospheric pressure, is the retardation of the circulation; in the majority of cases, the pulse is reduced from 100 to 45, or even less, in the minute. In four or five cases of inflammatory fever which I have treated in this way, the fever ceased after the first sitting; and in the case of my aunt, aged 74, the pulse, which was 120, fell to 60, and so continued. The explanation of this reduction of the circulation appears to me very simple. Submitted to a pressure greater than that of the atmosphere, the lungs find in an equal volume a much increased quantity of air. Respiration is rendered easy; the movements of expiration and inspiration less frequent to obtain the same result—the alimantation of the lungs. On the other hand, we know that, if we voluntarily quicken the breathing, the frequency of the pulse is increased: hence, if we place ourselves in such a situation that the number of inspirations be less, the frequency of the circulation will in the same proportion be diminished. This is precisely the physiological effect on the lungs, under the influence of the compressed air-bath.

The slowness of the circulation is not constant. It sometimes happens that it is increased. This effect is produced when the respiration is straightened or impeded; the compressed air restores it to its healthy state; and the acceleration of the circulation is the result of this return to the normal condition. It continues, when it is produced, only during the time of the sitting.

One of the effects of the employment of compressed air is the increase of secretion and of absorption. These two functions appear to depend on the increased activity of the venous circulation, which is always more active and complete while our organisation is submitted to a more elevated pressure.

In the majority of chronic affections of the respiration, the compressed air acts at first as a sedative; it relieves the symptoms, and the patient feels better; but generally, towards the twelfth or fifteenth bath, he is not so well, and experiences some return of the symptoms. This irritation may continue two or three days, but gives way to the employment of the same means. It is difficult to assign a limit to the duration of this mode of treatment; the mean time is about thirty or forty baths.

To give an account of the phenomena which present themselves in the treatment of chronic affections of the air passages, it would be necessary to enumerate them all successively; and they vary with the different cases. I have in no instance seen the employment of this therapeutic measure occasion any ill effect, or induce the patient to renounce it. All that I have treated have borne it without the least inconvenience. With regard to the principle of this healing influence, exercised in conditions so varied and so extensive, it connects itself with the powerful modification which the system of air-baths may introduce into the atmospheric fluid, in its various physical, dynamical, and chemical relations. The air-baths may also generally be united with any other medical or hygienic treatment.

They assist in the most remarkable manner the development of the constitution in infancy and youth, and render more firm the general health.

It is not our object to describe the various maladies which may be treated by the air-bath. We can, however, affirm that it may be used with success in all the chronic diseases of the air-passages, from the most simple catarrh to the most complicated pulmonary emphysema; and its curative influence is well marked. In the early stages even of pulmonary consumption, it may be advantageously employed. In some cases of this disease which I have treated, and which have been witnessed by Professor Bouisson of Montpellier, and by Dr. Devay, the success has fully justified our expectations.

Considered in a philosophical point of view, the compressed air-bath may be regarded as the subjugation of our atmosphere, by which we can increase or diminish the pressure which establishes the equilibrium of our organisation. In fact, we know that, in decreasing the surrounding atmospheric pressure, this equilibrium is broken, and sanguineous extravasations take place. The phenomena which present themselves in aërostatic ascensions are opposed to those which take place under the influence of compressed air, by which equilibration is kept up in all the functions.

Besides the physical condition of pressure, we can, through the aid of the same apparatus, convey chemical modifications to the atmosphere, and diminish or augment the proportion of its different gases. In one word, we can so far modify the atmosphere with which the Creator has surrounded us, as to render it more amenable to our wants and necessities. Regarded in this double point of view, this discovery marks a new era, and is a blessing to mankind. I feel myself honoured in devoting my efforts wholly to this undertaking—so full of hopes and promises for the future. To develop the beneficial effects of the air-baths, and to render the employment of them more general, and thus to multiply their advantages, will be my hope, and the end and ambition of my whole medical career.

Wirksworth, August 29th, 1853.

ON THE PATHOLOGY OF PHTHISIS.

By CORNELIUS BLACK, M.D.

As many members of the medical profession have requested from me an abstract of my researches into the pathology of pulmonary consumption—as several of my reviewers have expressed a desire for an early completion of my work “On the Pathology of the Bronchio-Pulmonary Mucous Membrane”—and as the immense chemical and microscopical labour necessary for the full and perfect investigation of the numerous data on which I proceed preclude the possibility of an immediate publication of part II, I may be permitted, in the meantime, to indicate some of the results at which I have arrived.

Assuming that the first substantive deflection from the standard of perfect health's in a deficient vitality of the formative elements of the blood, the origin, manifestation, and progress of pulmonary consumption are briefly enunciated in the following propositions:—

- I. That pulmonary consumption observes three stages.
 - a. The stage of Local Predisposition.
 - b. The stage of Deposition.
 - c. The stage of Germination.

II. That the stage of local predisposition is characterised by more or less excess of blood in the pulmonary capillaries of the affected part; that it corresponds to the first pathological condition of bronchitis and of pulmonary cellulitis; that the degree and extent of this local predisposition vary considerably; and that the resulting phenomena bear a proportionate ratio in point of severity and appreciability.

III. That the stage of deposition is attended by increased exudation from the pulmonary capillaries; that this exudation is incapable of entering into structural relation with the pulmonary tissues; that it leads to a more or less rapid thickening of the basement structure of the bronchio-pul-

monary membrane; that it likewise accumulates in the intervacular and intercellular spaces; and that the pulmonary tissue is thereby more or less consolidated.

IV. That the first appreciable sign of the stage of germination is a shedding of the epithelium of the affected portion of lung; that this epithelium does not attain perfect mucus-cell development; that in cases in which the deposition has been slow, it (the epithelium) is more granular than are properly developed mucus-cells; but that the epithelium is still more granular in cases of rapid tubercular deposition.

V. That the epithelium thus shed is not, in progressive tubercular disease, replaced; that, so long as a particle of healthy basement structure exists, the nuclear points of that structure attempt to replace such lost epithelium; but that this properly vitalised basement structure failing before such attempt at the restoration of the epithelium has succeeded, the latter is now cast off in the form of basement patches, which show, here and there, a germinating point.

VI. That the tubercular deposit undergoes, during germination, more or less development into cells; that this growth constitutes the “softening” of authors; that it takes place contemporaneously throughout each isolated and individual mass of tubercle; that it, therefore, does not first commence at either the centre or circumference of the exudation; but that it proceeds more rapidly at the circumference, because at this point the conditions of cell growth are more abundant than at the centre. At the circumference, therefore, plastic and pus-cells abound; at the centre, exudation-cells.

VII. That in the cheesy looking portions of tuberculous sputum there are very frequently, indeed, portions of nerve tubes, and occasionally of lymphatic vessels and of the minute bronchi; that, in other portions of such sputum, plates of cholesterine, the colouring matter of the bile, cystine, and urate of ammonia are occasionally seen by the microscope.

VIII. That the microscopic appearance of the nerve-tubes thus expelled shows that the nerves do not terminate in loops upon the pulmonary mucous membrane, but in bulbous expansions, to be hereafter depicted.

IX. That the foregoing observations show pulmonary consumption to consist in abnormal nutrition, and to be essentially analogous, in its steps, to inflammation; but that the term “inflammation” would be inapplicable to it, inasmuch as it fails to explain the cause of the deficient vitality of the blood-plasma, which constitutes the essential nature of tubercle.

Chesterfield, August 29th, 1853.

CASE OF DOUBTFUL SEX.

By JAMES M. CHURCHILL, Esq.

MR. MANN's case of doubtful sex, published at p. 720 of the ASSOCIATION JOURNAL for August 19th, induces me to give another.

I was requested to see a young person, aged twelve years, who had been brought up as a female. From the outward appearance, I should not have known that the individual was not a female. I found a penis in miniature, with distinct glans, corona glandis, and præputium, as in Mr. Mann's case; but the urethra was situated just as it commonly is in the female, and the vulva was also exactly in appearance that of a female of similar age. I delayed further investigation for a year, at the expiration of which period I found a scrotum on the right side, containing a testicle; and, six months afterwards, another testicle descended on the opposite side. Soon after this, he lost his parents, and went to London, where the male dress was adopted. He had been sorely perplexed to determine which trade would be the least likely to expose his infirmity; but at last he adopted that of a confectioner. This may be a useful hint to others of doubtful sex.

Colchester, Sep. 2nd, 1853.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

CHLOROFORM IN HOOPING-COUGH.

Dr. FLEETWOOD CHURCHILL, of Dublin, in the *Monthly Journal of Medical Science* for August, addresses a letter to Professor Simpson upon the use of chloroform in whooping-cough. The following is an extract:—

You are aware that, in my work on *Diseases of Children*, published three years ago, I mentioned that I had tried the inhalation of sulphuric ether in whooping-cough with great benefit in about a dozen cases. After your application of chloroform for producing similar results, I tried it in whooping-cough with equal benefit in at least as many more cases. But I always found two obstacles to its full and fair administration to young children. In the first place, you cannot get them to give notice of the approach of a cough, so as to enable you to have the chloroform in readiness before the paroxysm commences, and when the paroxysm has commenced, as it consists of eight or ten expirations to one inspiration, the chloroform will have evaporated before it has been fairly inhaled. And secondly, young children have such a horror of anything near their mouths during the cough, that they will resist your trying the chloroform as much as possible, until they themselves have felt its power in relieving the cough. Owing to these two causes, and perhaps also to a want of clever management on the part of the mother, we shall find it fail altogether, occasionally, and in other cases only partially succeed; but when it is fairly tried, as I have already remarked, its use is most beneficial.

I have all along felt very anxious to try it in young persons of twelve or fourteen years old and upwards, because with them we can avoid the two difficulties I have mentioned; but it was not until this year that I had an opportunity. Four cases have come under my care, and the results are as follows:—

CASE I. Miss D., aged 16, had had whooping-cough a month, when I prescribed chloroform. There was no complication, but the whooping was frequent, especially during the night. She was directed to have the chloroform in readiness, and to use it with each paroxysm, and she assures me that in two days the whoop ceased. The cough lasted a few days longer, but it was slight and not in kinks.

CASE II. Miss A., aged 20, had been ill with whooping-cough for about three weeks, when I prescribed chloroform. The cough was not very frequent, and there was no complication. Two days sufficed with her also to relieve her of the whoop; and the slight cough which remained subsided after a week or ten days.

In these two cases the effect seemed quite magical; both had the disease well marked, and the families of both were prepared for a disease of two or three months' duration, as was the case with their other children.

CASE III. Miss B., aged 18, took the complaint from her brother whom I was attending, and I therefore had an opportunity of giving chloroform from the commencement. She did not whoop any time she coughed; but she was directed to use chloroform whenever she felt the tickling in the larynx, without waiting for a cough. By doing so, she found that she could postpone the cough indefinitely, and if it came on suddenly, the use of the chloroform instantly suspended it. About three weeks elapsed before the tendency to cough and the use of chloroform ceased; but during that time she lost neither appetite nor flesh. She slept well, was in good spirits, and able to follow her usual occupation. She went to the country quite well.

CASE IV. Master B., aged 16, the brother of the last case, when I first saw him, had the disease most severely. The kinks were violent and prolonged, the efforts to inspire, and the whoop excessive; it really seemed as if he would be choked or that something would give way. He had lost appetite, sleep, and spirits, although the disease had not lasted three weeks when I saw him. I tried chloroform with him, and it at once reduced the number of paroxysms one half, but without mitigating them when they did occur. He took the chloroform very freely, and as he was not readily influenced by it, the quantity seemed to give him a headache, and he begged to be allowed to suspend its use. I the more willingly agreed to this, as he had a severe attack of diarrhoea. I therefore substituted two drops of prussic acid (Dub. Pharm.) with two or three of black drops three times a day. The improvement,

begun under chloroform, continued under this treatment, and at the end of five weeks from the beginning of the disease the cough had ceased, and he had regained rest, spirits, and flesh.

Although this last case cannot be regarded as cured by chloroform, the paroxysms were first diminished by it, and I have no doubt that it contributed to the beneficial effect of the prussic acid. The three first cases are, I think, very conclusive as to its value; and, if further experience confirms them, we shall possess a means of cutting short this disease in adults, who, when attacked, suffer so severely.

CONSTIPATION AND FÆCAL OBSTRUCTION.

Dr. CHRISTISON, of Edinburgh, publishes the following very interesting extract from a Clinical Lecture, in the *Monthly Journal of Medical Science* for September, p. 252.

The occurrence of a singular case of obstruction of the intestines from accumulation of feces, induces me to make a few remarks on a subject which, though it may appear trite to you, is really one of great importance, and deserving your early consideration as professional men.

When you enter presently on medical practice, you will probably be surprised, as I was in the same conjuncture, at the exceeding frequency of the habit of constipation among persons in easy circumstances in this country. At what period this liability was first observed, and in what cause or causes it originates, are questions which at present I cannot pretend to discuss. But there can be no doubt of the fact, that the infirmity of constipation is extremely common; and likewise, that it often exists without any other constitutional infirmity or special disease, except what is clearly referable to an undue neglect of the proper correctives. Accordingly, by due attention to the use of fit laxatives, thousands of persons of both sexes in the middle and upper walks of life contrive to live as long, as healthily, and, except for the plague of constantly taking physic, as happily, as their more fortunate neighbours.

Prior to the publication of the treatise on purgative medicines by the late Dr. Hamilton, senior, of this city, there is much reason to believe that the use of laxatives was greatly neglected in such circumstances. But after the appearance of that work in 1818, an important reformation took place in this respect. Indeed, as in all important reforms in medicine, physicians and their patients soon ran to the opposite extreme; and ere long as much harm was done by the abuse of aperient and purgative medicines as previously by the neglect of them. At present it may be confidently said that both errors have been materially corrected. No one denies the great importance and frequent necessity of cathartics of all kinds, from the mildest laxatives up to the most drastic purgatives. And on the other hand, most physicians are now satisfied that gentle aperients are sufficient in numberless circumstances, in which formerly powerful cathartics were the fashion. Among other observations, too, it has been found that the regular daily use, even of mild laxatives, is not so indispensable a precaution for preserving the health of those of a permanently costive habit, as has been supposed by many physicians, and especially by many people themselves who were afflicted with that habit. For example, there can be no doubt, that for most people, who, though otherwise healthy, require constantly to use aperients, it is better to open the bowels in this way once every other day only, than daily by a daily dose. Some, especially those who live freely, require a more frequent dose. But in general you will find an effectual aperient every other day amply sufficient for those who do not augment the bulk of the alvine discharges by superfluous nourishment; and by that system they are much more likely to escape the risk of an irritable or congested state of the intestines arising, which we know to be the frequent consequence of the habitual excessive use of cathartics, even of a mild kind.

Some persons, however, have such a horror of aperient medicines, that they cannot persuade themselves to take one oftener than twice a week, or once a week only. And, nevertheless, you will sometimes see them keep their health, and maintain their bodily comfort. But, for the most part, you will find it a sound general rule, to insist with such people on a more liberal use of aperients; and the great variety we now possess of convenient compound aperients, will enable you to find some one suitable to the constitution of any body, and reconcilable with almost any prejudices.

There are others, whose prejudices are unconquerable, and who will not take laxatives at all, though their bowels do not move of themselves above once a week, if even so often. And it is right you should be aware that this apparently most natural and preposterous habit is not of necessity, and

cases, a habit injurious to health. You will occasionally meet with men so singularly constituted, that they enjoy sound health upon a weekly stool. And, indeed, all perhaps that can be said of them is, that they are rather to be envied by their fellow-creatures, for an endowment which must be frequently found very convenient. But such people sometimes get into difficulties. About two years ago, a gentleman from Wigtonshire, a landed proprietor, attached to agricultural pursuits, and therefore never without free air and exercise, consulted me about a serious difference he had with his medical advisers in the country. Having recently recovered under their care from a severe pneumonia, they made the not unreasonable stipulation, when they ceased to attend him, that he should take a laxative every three days, to correct a constipated habit. To this he demurred, on the very natural ground, that, until his late illness, he had enjoyed excellent health for sixty years, although his bowels had been habitually moved all his life only once a fortnight. This gentleman had made a journey of a hundred and twenty miles, for no other reason than to get the question between him and his physicians settled by some competent authority in therapeutics; and, in referring to me for the purpose, he mentioned, for my further guidance, that a neighbouring gentleman of his acquaintance, of the age of seventy, had told him that he too had immemorably evacuated his bowels only every alternate Sunday, without being able to recollect having ever had an illness. It was scarcely to be wondered at that their common experience half inclined them to think that their constitution was the natural and patriarchal one.

Our hospital patient seems to have been of the same opinion with these elderly agriculturists. Like them he has had some experience of life, being now 74. Like them, too, he has enjoyed singularly good health, being a surprisingly fresh looking man for his years, notwithstanding that he had passed through severe trials in early life. As a soldier in India, he sustained, when very young, a spear wound of the leg, where he has had, almost ever since, a small open ulcer, which he ascribes to the spear having been poisoned. In the Spanish war he was wounded at the battle of Barossa, in 1811. There are now evident marks of the bullet having passed through him from the left groin, piercing the blade of the *os ilium* in its course. For two years he lay in hospital; and recovering with a shortened limb and stiff joint, he was invalided on a pension of one and sixpence halfpenny, as a wounded serjeant and soldier of twenty-one years' service. This he has now enjoyed for forty-one years. Nor has his wound much incapacitated him; because for many years, and down to his present illness, he had actually worked as a railway labourer. During this long period he lived on his pension and wages in great comfort and sound health, until, on lately leaving off work, he became liable to constipation. At first his bowels were moved every other day in general, and afterwards seldom oftener than once a week, unless he took physic, which he did seldom. At last the action of the bowels seemed to cease altogether, and he went for four weeks without any evacuation, even though he made occasional trial of a laxative. At the end of the fourth week, a strong dose brought away a great accumulation. After that he had no farther evacuation, and it is now three weeks ago. He had again made a few gentle attempts to assist nature; but he did not much insist upon this, because his lodging-house had no convenience, as he said, for a man under physic. During the entire period of seven weeks, he assures us he had no pain or suffering whatever. But at last his belly got very large, so that his trousers would not button over it; and on this account he applied here for relief, and not from any actual illness.

On admission, he had no appearance of any suffering. He seemed a fresh, vigorous, active, cheerful man. He took his food tolerably well; the pulse was natural; and the tongue was only a little furred. "The abdomen", to quote the Hospital journal, "is much distended, especially in the iliac regions, where there are two large prominent swellings projecting laterally, so that the crest of the ilium on each side is quite sunk, the tumours projecting much beyond the bones. There are different irregular swellings at different parts of the abdomen, especially in the track of the colon. Over some of these points percussion is quite dull; over others it is tympanitic. The circumference of the abdomen, where largest, is 39½ in."

As it was judged unsafe to give him active purgatives by the mouth at once, in case of the great gut being firmly obstructed with hardened feces, a turpentine injection was properly administered by the clinical clerk in charge of him. The result was "a prodigious discharge of fecal matter of all degrees of consistence", much of it composed of very hard scybala. A dose

of jalap and calomel given immediately after this forerunner, brought away also a great mass of feculent matter. Next day, being quite well, but with the abdomen as large as ever, another similar dose occasioned only an ordinary discharge. On the third day, the swelling being equally great, though now quite uniform, and everywhere clear on percussion, I gave him what has always appeared to me the most effectual of all safe energetic purgatives in cases of simple fecal accumulation—two drachms of oil of turpentine with six drachms of castor oil in the form of emulsion. But he had only two scanty loose discharges, and the belly continued in the same state, presenting especially the singular enlargement and overlapping of the iliac regions.

It was now apparent that, owing to long continuous distension of the bowels with feces and gases, their muscular coat had lost its tone, in some regions at least, and especially in the cæcum and descending colon. It was then proposed by the clinical clerk to resort to galvanism for relief from this paralytic condition; which suggestion was at once adopted. It is more than twenty-five years since galvanism was recommended as a useful remedy in cases of obstinate constipation; and we can easily see that it may be useful, and upon what principle it acts. The first way of using it was by directing the galvanic current from the mouth to the arms; and in that way it seems to have been most effectual and prompt in some cases. But its action is thus rather painful; and ulterior observation has shown that passing the current in various directions through the abdomen itself may be sufficient. This remedy seemed even more applicable to the state of our patient after the bowels had been cleared out. And accordingly it acted with wonderful energy and success. After the current had been passed for some time from before backwards, as well as from side to side, he had in an hour a copious evacuation, in three hours another, and next morning a third. Flatus was also discharged in abundance; and the abdomen fell greatly, but still not completely, above all in the iliac regions. The pain of the galvanic action, however, had been so great that the patient begged to have a day's respite. In fact, he declared his willingness, and confirmed it with an oath, that he would rather be shot again than submit to be galvanised a second time. On the second morning, however, the remedy was applied more gently, and on two mornings subsequently. He had a daily discharge from his bowels, and sometimes two. The abdomen had now become natural in size and form. Since then he has had a natural evacuation every morning without aid from either laxative or galvanism. He was dismissed after being fourteen days in hospital.

This is a case a little out of the common run, but not without instruction; and I have therefore thought it well to bring the chief circumstances under your notice. It is an excellent illustration of the influence exerted by galvanism over the animal functions. It appears to me to hold out a probability that the same remedy may prove serviceable in restoring the tone of the intestinal muscles, in other forms of inconvenient chronic flatulent distension of the abdomen.

TURPENTINE VAPOUR BATHS.

The *Union Médicale* for July 16 and 19, copies from the *Revue Thérapeutique du Midi*, an article on turpentine vapour baths, by Dr. A. AILLAUD, of Beaucaille.

According to Dr. Aillaud, the peasants of Vercars have long been in the habit of employing turpentine vapour baths in catarrhal affections; and this practice has been confined to them.

The apparatus used is first described. It consists of an oven, resembling an egg cut in two, and having at the top an opening closed by a valve, and having at the bottom a grating. The oven is built of stone, with thick walls. When it is required to be used, the grating is scattered with chips which have been hewn from the living trunk of a peculiar kind of pine, which is only met with in the forests of Glandaz, and which is very rich in resinous and terebinthinous principles: fire is applied to the chips, and the valve is opened that the smoke may escape. Combustion continues several hours; its end is announced by the cessation of the formation of pitch. The valve is then closed, so as to extinguish all traces of fire; the ashes are then quickly removed, and the opening by which this is done is carefully closed. At the end of more than eighteen hours, there is still a temperature of from 60 to 80 degrees of Reaumur (107 to 212 degrees Fahr.) Some fresh chips are then placed on the grating, and the patients are introduced into the oven, through a thin iron door in the wall. Benches are placed around, on which the patients sit, with their feet resting on the grating. They are thus exposed to the action of medicated vapours.

They reach the door of the oven by a corridor, having a temperature of from 40 to 65 degrees of Reaumur (122 to 178 degrees Fahr.); they remain here a few minutes, and then enter the oven. Their dress is a white woollen shirt, and woollen slippers. They remain in the oven ten, fifteen, twenty, or thirty minutes: the effect is observed by a medical man stationed at the door of the corridor.

The patients first experience a sensation of excessive heat, which they think they cannot endure, but which in the end becomes even agreeable. Under the stimulating influence of the heat, diaphoresis takes place; it is at first very slight, but soon becomes copious: it commences on the chest, and gradually passes over the whole body. Respiration is accelerated for a few moments; but in two or three minutes becomes easy. The circulation becomes a little more active: sometimes the pulsations rise to 70 or 80; sometimes they remain normal. When the desired effect is produced, the patient is removed from the bath; a woollen covering is thrown over his shoulders, and he is carried to bed, where he takes an infusion of the same resinous wood. The diaphoresis then becomes sometimes so copious, that it escapes through the bed-clothes. At the end of an hour or two, the patient rises as alert and lively as before he entered the bath: he feels none of the disagreeable sensations which accompany or follow febrile sweats. His functions are performed with ease and regularity.

Dr. Aillaud observes, that this treatment includes two distinct principles: the application of heat, and of resinous vapours. He then proceeds to describe the effects of placing a person in a high temperature: increase in the heart's action, hyperemia of the surface, and also of the lungs, inducing increased activity of respiration, which is at the same time accelerated by the rarefaction of the air; and hence symptoms of syncope. Dr. Aillaud sums up the symptoms produced as those of a factitious fever; and he believes that great advantage may be derived from the excitement of fever in almost all chronic diseases, where there is no organic lesion present. As examples of this, he refers to acute diseases which have been badly treated, and have become chronic; and also to chronic, nervous, and spasmodic diseases, connected with a morbid principle.

The utility of balsamic medicines in chronic catarrhal and rheumatic affections, has been known from the days of Hippocrates and Dioscorides; and is the mode of administration to which Dr. Aillaud wishes to call attention. If a medicine acts more energetically the better it is absorbed, and the more it is in a divided form when taken, we may judge of its power according to the manner in which absorption has taken place, and especially from the characteristic odour which is assumed by the excretions of the persons who have been in the bath.

The pulmonary mucous membrane participates in the effects produced by turpentine on the other mucous membranes. Hence the membrane, under its influence, becomes dry, as in the early stage of bronchitis; and some individuals in these circumstances expectorate sputa streaked with blood. It is in the chronic mucous bronchitis of lymphatic old men that the turpentine vapour bath is most useful. The bronchial mucous membrane is generally pale, but of normal thickness and consistence; the principal change consists in tumefaction of the follicles, and more or less considerable dilatation of the bronchial tubes. The symptoms have a great resemblance to those of the third stage of pulmonary phthisis.

Dr. Aillaud answers the objections that exposure in the turpentine vapour baths may produce impeded respiration, and that it is dangerous for apoplectic patients, by stating that no bad results have been found to follow in any case.

tion of the knowledge that might be derived from such a study in inquiries directed to the causes of various diseases, has long been known and proclaimed. Arbuthnot, in his essay on the "Effects of Air on Human Bodies", affirms in one of his concluding paragraphs, "that from proper journals of the weather, it might be possible to predict epidemics." And several observers of a past age, amongst whom the names of Mussenburgh, Vitet, Hans Sloane, and Ramazzini deserve especial mention, actually made laborious attempts to discover how far meteorological observations could be made of use in accounting for the origin and spread of some diseases. From an ignorance, however, of many important physical laws, the discovery of which has been reserved for modern days, the labours of these observers proved of but little value; so that, whilst few facts have been established, a vast number of vague impressions and wild theories have taken root and flourished.

Even in this day, as you observe, we have "no strict scientific knowledge of the nature and operation of atmospheric changes upon the body in health and disease". The step, therefore, which you are about to take, the endeavour to enrich our stores of medical learning by a systematic inquiry into the effects of meteorological changes on the body, is almost a new feature in medical literature, and promises to do great honour to our Association, and to the Journal in which the opinions and observations of the members of the Association are recorded.

That the table you are to publish weekly, is an improvement on the one already published by the Registrar General, is very evident. One important improvement in your table, lies in the fact that the observations given are to be made in different parts of the country. At the same time, it occurs to me that two or three additional columns are required. A column describing the electrical states of the atmosphere, like that in the table of the Registrar General, would be added with advantage; for although it is possible that far too great an importance is attached by many persons to electrical conditions, I think that, to ensure correctness, all known electrical phenomena should be carefully noted down. Secondly, the place where the observation is made should be supplied; and thirdly, the *nature of the earth's surface at the point of observation should be clearly specified*. I dwell on this last suggestion, because I believe it to be an important one. Meteorological observations can, as a general rule, be made by professional men but once or twice in the twenty-four hours, and only in the day time. Now, one of the most important changes in relation to the body, is that of its transmission from a cold to a warm temperature, the change consequent on the withdrawal and the return of the sun; and this change will vary very much at different points of observation. At some points, the sun's heat during the day will be absorbed slowly, to be evolved slowly during the night; at other places, there will be little absorption in the day, and rapid radiation and rapid cooling of the earth and of the atmosphere in the night time. Other observations, also, touching the geological nature of the district, deserve especial regard. In short, in commencing your labours, no inquiry that promises an useful result should be omitted; for disease arises in many cases, not so much from the exposure of an animal body to influences that are injurious to it, as from the *rapidity* with which it has been subjected to those influences.

Another observation should be made, having reference to the effects of light and actinism on the animal body. It is fair to infer that no meteorological table can be perfect without such observations; for that the properties of the sunbeam, to which reference is now made, exert an influence on the living world, animal as well as vegetable, no one can deny. Our ideas on the subject are vague at present; but this is the very reason why knowledge respecting it should be increased. That influenza is more prevalent on the shady than on the sunny sides of streets; that cretinism is most common in valleys, where light is in some degree absent; and that animals may have diseases induced in them by being placed in absolute darkness;—these are all ideas which many professional men hold, but they are ideas altogether unproven. It may be objected, that it would be a difficult matter to make observations on light—an objection, indeed, in which there is some degree of truth. It would not, however, be a more difficult process to test for the *actinic principle* of the solar ray, than to test for the presence of ozone.

In looking over the interesting calculations of Dr. Moffat which you have transcribed, it is a source of infinite surprise and pleasure to me, to see that that gentleman thinks he has pointed out a connexion between meteorological conditions and the presence of certain diseases. During last winter, whilst

EDITOR'S LETTER BOX.

MEDICAL METEOROLOGY.

LETTER FROM B. W. RICHARDSON, ESQ., TO THE EDITOR.

SIR,—A perusal of the leader on medical meteorology, contained in the Journal of August 26th, has given me so much pleasure, and filled me with such hope for the future, with reference to the investigation of numerous difficult questions connected with the study of disease, that I cannot avoid turning for a few moments from an interesting inquiry, to make one or two observations on your extensive, well digested, and admirable scheme.

The importance of the study of meteorology, and the applica-

engaged in preparing a paper to be read at the Epidemiological Society (which paper has since been published in this Journal), I tried to investigate the subject now referred to. Taking the returns of the Registrar General, and assuming that the rate of mortality of the epidemic diseases was an indication of the prevalence of those diseases, I endeavoured to ascertain whether any particular meteorological condition, or any series of meteorological conditions, attended an increased or decreased rate of mortality. In this way I took up with great care several diseases—scarlatina, small-pox, measles, and whooping cough, especially. Then selecting certain weeks, out of a series of years, in which the mortality figure was the same, I referred to the meteorological tables of the same weeks, to see if a relationship of any kind could be traced. The results were all negative. The same meteorological conditions that were present at one time, when the mortality of a disease (I allude to scarlet fever more particularly) was highest, say 188 per week, would be present also when the mortality of the same disease was lowest, say 8. In fact, I could make out nothing whatever. To be sure, the observations of the Registrar General were not very applicable to my purpose, inasmuch as they did not give every meteorological condition, were made at one point only, and were not strict enough in the matter of time; but still it is curious that the results of my inquiries were so decidedly unsatisfactory, and I am bound to confess that even the more careful researches of Drs. Moffat and Tripe do not lead me to alter an opinion elsewhere expressed, that as yet we are quite unable to refer the presence of any disease either to a single meteorological condition, or to a combination of meteorological conditions. Of course, I repeat this opinion with great deference; and sincerely trust that it may in the end prove to be incorrect. It is no intention of mine to say that the external influences to which we are exposed produce no effects on our bodies; on the contrary, I recognise the full importance of those influences, and am only desirous of seeing their effects more thoroughly investigated.

And while I am speaking of the external agents that surround and exert an influence over the living being, I cannot but observe, sir, that the course you are about to pursue will, by opening the eyes of the profession to the nature and importance of those agents, lead to an improvement in the treatment of disease. For three or four years past, my mind has been directed to this matter. I have made it a point to observe, if I may be allowed the expression, *the effects of the meteorological changes of the sick room*; and I do assure every one of my professional brethren who may not have paid attention to the subject, that it is not only an interesting, but a highly important subject. It is in the treatment of pulmonic complaints that the condition of the atmosphere of the room should be most studied. I fully believe that it is well nigh in vain for a medical man to treat a case of pneumonia or bronchitis, if, in his absence, the management of the fire in the room of the patient is left to the unchecked hands of a nurse. Let the temperature of the room of a patient suffering from these diseases rise only a few degrees above 60° Fahrenheit, and let the atmosphere of the room become too dry, and so much is the respiration of the sufferer increased, and so rapidly does the oxidation of the body proceed, that antiphlogistic and all other remedial measures will at least be much modified, and perhaps be nullified altogether. In short, in the treatment of many pulmonic complaints (there is not time to allude now to other diseases) I do not hesitate to say that the hygrometer and the thermometer are, in the hands of a scientific physician, as useful and as necessary instruments as are the stethoscope, the lancet, and the drug to be prescribed.

But I must not now encroach further on your columns. That your meteorological table will accomplish great things in the end there is no doubt, and I think I see many of our colleagues who, having read your leader, feel as much unexpected gratification, as I do myself. The instant your project is set on foot, an attempt is being made to correct errors, that may almost claim the year one as their birth year; and if any other word of commendation need be added, it is, that the benefits likely to arise from your labours, and from the labours of the distinguished individuals who work with you, are addressed to the whole human family, to the present time, and to all time.

I am, etc.,

BENJAMIN W. RICHARDSON.

Mortlake, September 5th, 1853.

MEDICAL METEOROLOGY.

LETTER FROM HENRY W. BAILEY, Esq., TO THE EDITOR.

SIR,—Your elaborate paper upon Medical Meteorology, is one of so important a nature, that it requires the consideration of every medical practitioner. It is so intimately connected with disease, with the history of epidemics, and with the progress of various diseases, that its study would prove highly beneficial to the public health, as well as promote the knowledge of meteorological science. By a regular series of observations, made in different parts of this kingdom, or even the world, we may be enabled to form accurate deductions. With this view was instituted the London Meteorological Society, of which I was one of the earliest members; and, at the first meeting, good earnest was evinced by establishing eight stations for observations. Thetford was one of them. A report was sent monthly and laid before the Council. I regretted to find very few medical members were enrolled; and I fear, in the present instance, from their continual occupation, you will not receive many of those contributions so much to be desired. No persons are more qualified than our profession to promote such scientific study. I regularly sent my reports, and they did me the honour to insert them in their first volume of Transactions. The two monthly reports I have enclosed for your inspection, are specimens of the plan I have pursued for thirty-six years. By comparing them with the register at the Royal Observatory, you will find but little difference, allowing for locality. However, such a schedule would be unfit for the object in view. Diseases might be recorded as occurring under a certain atmospheric pressure and temperature. The humidity of the air bears a considerable part: from my observations, I have invariably found fever, catarrhal affections, cynanche tonsillaris, and any epidemic present, much aggravated; while in a higher pressure, low temperature, and moisture, inflammatory diseases, as pleurisy, rheumatitis, influenza, etc., more prevalent. Some considerable information may be derived from this branch of study, as to the laws which govern or produce epidemics, or even contagious diseases arising from cesspools, etc. Much has been attributed to the latter; but probably arising from certain states of atmospheric pressure, etc., which has escaped the attention of the contagionists. It is very certain that the various changes in the atmosphere have great influence upon the human system; and those in the lower grade of society, where much deprivation is experienced, are more subject to diseases from such causes, and there now wants only a neglected cesspool or privy to account for the disease under which they suffer. The nuisance act and sanitary laws come to our assistance; but these avail but little, unless the means are provided to better the poor man's condition as to food and proper quantum of nourishment. In this locality, since the cheapness of provisions, there has been considerably less of disease among the poor than I ever observed before, although there remained the same nuisances at the door.

I hope, sir, your laudable intentions of promoting the study of medical meteorology will be fulfilled, as you will thus confer a great benefit upon the public.

I am, etc.,

H. W. BAILEY.

Thetford, Sept. 3, 1853.

THE NEW ECONOMIC LIFE INSURANCE OFFICE.

LETTER FROM HENRY TERRY, Esq., TO THE EDITOR.

SIR,—I shall be much obliged if you, or any of your numerous readers, can give me any information respecting the "*New Economic Life Insurance Office*", 12, Took's Court, Chancery Lane, London, of which Mr. William Deacon is secretary. A few weeks ago, a respectable tradesman of this town was induced to insure his life in an office of that name, and applied to me as his ordinary attendant to fill up the requisite certificate. As I had not heard of the office previously, and could not find its name in any list, I cautioned my friend. However, he would not listen unto my advice, and sent up a P. O. order for £2, which he had been assured was necessary for preliminary expenses, and would be returned if his life was accepted. As might be expected, he has had no answer. At the end of a week I wrote a civil note to the secretary requesting my fee, which has met with the same fate. You will agree with me that, in the absence of further explanation, the "*New Economic*" does not bear a very good character.

I am, etc.,

HENRY TERRY, JUN.

Northampton, August 29th, 1853.

NEWS AND TOPICS OF THE DAY.

[Continued from page 788.]

MONTHLY JOURNAL OF MEDICAL SCIENCE. The September number has appeared without the names of the "conductors", viz., Dr. Christison, Mr. Syme, Dr. Simpson, Dr. Hughes Bennett, Dr. Douglas MacLagan, and Dr. Wm. Robertson. It is not known how many, or whether any, of these gentlemen have withdrawn from the management; but it is generally understood that the polemical energy of the Journal is to be moderated.

NORTH BRITISH MUSEUM. For some time past, an agitation has been going on in Scotland, in favour of what is called "Justice to Scotland"; and it appears that, as the first fruits of this movement, government are to sanction the erection in Edinburgh of a National Museum—a North British Museum. A fortnight ago, the Right Hon. Edward Cardwell, President of the Board of Trade, accompanied by the Lord Provost, Bailie Morrison, Bailie Fyfe, and Mr. Hall Maxwell, Secretary to the Highland Society, visited various sites which have been suggested as suitable. Mr. Cardwell met the gentlemen we have named at the University, and, after inspecting the splendid collection of specimens there which are rendered entirely useless for want of proper accommodation, he examined the area behind the College, occupied by the Rev. Dr. Alexander's Church, and by the Trades' Maiden Hospital. The party then proceeded to the Museum of the Highland and Agricultural Society, on George the Fourth's Bridge, where the right hon. gentleman had pointed out to him another of the proposed sites, lying between that building and the Cowgate. Lastly, he visited the County Buildings, where the party was joined by Mr. Sheriff Gordon. Mr. Cardwell heard all that was advanced in favour of the different sites; but he did not commit himself to any particular one. The general feeling in Edinburgh is in favour of the site behind the College. This is the site which the Lord Provost and those representing the Town Council consider to be the best; and we believe the Highland and Agricultural Society are of the same opinion, although they would much prefer that the ground near their own Museum should be fixed upon, rather than the County Buildings. It is not yet known, we believe, whether government will give a grant for a Museum of Practical Geology merely—similar to those recently established in London and in Dublin—or whether they will be prepared to allow a sum sufficient for a Museum of a much more extended character, including the former as a mere branch. The latter is the plan most likely to be adopted.

ARTIFICIAL PROPAGATION OF SALMON. A meeting of the salmon fishing proprietors in the Tay was lately held at Perth, for the purpose of considering the question of the artificial propagation of salmon. Mr. Thomas Ashworth, from Ireland, stated that his brother and he have, at the present time, about 20,000 young salmon in ponds, produced by artificial means. His brother and himself, having purchased "the Galway Salmon Fishery" in Ireland, they determined to try an experiment there for the artificial propagation of salmon. A suitable place having been fixed upon at Outerard, operations were commenced between the 20th December and the 1st of January last, which was about a month too late. Boxes were prepared in which the spawn of the salmon were deposited: these boxes were about eighteen inches square and six feet in length, with a zinc grating in the sluice at either end. There were twenty boxes in all, which were filled with gravel to the depth of six inches. To procure the ova and milt of the female and male salmon, the fish were taken by small nets on the spawn fords at night, and instantly and without injury put into a tub one-fourth full of water. The female fish was first turned on her back, one man holding the tail, another running his hands down each side from the head, and, pressing lightly with his thumbs, the ova was readily discharged into the tub: a similar course readily discharged the milt. About 370 salmon were treated in the above manner, and again returned to the river. Mr. Ashworth explained how the ova and milt were mixed in the tub, and then taken out of it with a cup and deposited in the boxes, when it was covered with additional gravel. The fine zinc gratings were used to prevent both trout and insects from getting into the ponds, as they were very destructive to the salmon-fry. The ponds were about twenty yards in length, and twelve to thirteen yards in breadth; and it was intended to

keep the young salmon in them for ten months, when they will have grown to about four inches in length. They would then be able to take care of themselves on their way to sea. He stated also that it was indispensable the young salmon should be fed daily with chopped flesh meat. The current of water running through the boxes must be pure and free from mud, and great care was required during the periods of incubation, when the rivers were flooded by heavy rains, to divert the muddy water from the boxes. It took about 100 days until the spawn gave indication of life. The expense of this plan of artificial propagation he did not estimate to exceed a pound a thousand, which was at the rate of one farthing for each salmon. After some discussion, it was resolved that the experiment should be tried in the Tay; and a committee was appointed to adopt the requisite measures.

ST. THOMAS'S HOSPITAL. The Estate Committee of this hospital have recently let on lease for eighty years a small portion of land belonging to their corporation, at the north-west corner of Finch Lane, of about four hundred square yards, to the Australasian Company, at the enormous rent of £1,300 a year, with the condition to build on it a substantial stone building. This letting, if calculated at its freehold value, at the present price of Consols, would represent the extraordinary sum of rather more than £520,000 per acre.

MEDICAL BENEVOLENT COLLEGE. At a meeting of the Council, held on Tuesday last, thanks were voted to the Rev. Thomas Bazeley, the rector of Poplar, for preaching in aid of the funds of the College. The Treasurer reported that Dr. Kenny, of Canton, had, unsolicited, advocated the cause of the College in that distant country, and had remitted 222 dollars (£55:10), as the result of his disinterested exertions. Many of the Chinese are liberal contributors.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ADVERTISEMENTS.

Just Published, 8vo, price 2s. 6d.

Practical Observations on Deafness

and DISEASES of the EAR ARISING from the EXANTHEMATA. By PETER ALLEN, M.D., F.R.S.

London: LONGMAN, BROWN, GREEN, and LONGMANS.

MR. PAGET'S LECTURES.

Just published, in 2 vols. 8vo, with numerous Wood Engravings, price 28s. cloth.

Lectures on Surgical Pathology,

delivered at the Royal College of Surgeons of England. By JAMES PAGET, F.R.S., lately Professor of Anatomy and Surgery to the College; Assistant-Surgeon and Lecturer on Physiology in St. Bartholomew's Hospital.

. The Second Volume, comprising LECTURES on TUMOURS, may be had separately, price 16s.

London: Longman, Brown, Green, and Longmans.

Just Published, price 5s.

On Rheumatism of the Head and

EAR, and on SOME FORMS of HEADACHE in CONNEXION with DEAFNESS. By WILLIAM HARVEY, F.R.C.S., Surgeon to the Royal Dispensary for Diseases of the Ear.

Also, by the same Author,

On the Enlarged Tonsil, and some Affections of the THROAT in RELATION to DEAFNESS. Price 3s. 6d.

London: HENRY RENSRAW, 356, Strand.

Mental Derangement.—Dr. Samuel

G. BAKEWELL receives under his care, in the neighbourhood of Church Stretton, Salop, a limited number of Gentlemen and Ladies suffering from MENTAL DERANGEMENT, in separate houses, sufficiently near to each other to be under his personal superintendence.

The ESTABLISHMENT FOR LADIES is under the immediate care of Dr. and Mrs. BAKEWELL, who reside in it, and a Medical Superintendent resides with the Gentlemen.

The neighbourhood of Church Stretton is retired and healthy, and its scenery eminently beautiful and picturesque.

References are permitted to Dr. HENRY JOHNSON, Shrewsbury; FREDERICK CARTWRIGHT, Esq., Oswestry; and other medical gentlemen.—Church Stretton is a first class Station on the Shrewsbury and Hereford Railway, 12 miles from Shrewsbury.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXXVII. LONDON: FRIDAY EVENING, SEPTEMBER 16, 1853. NEW SERIES.

THE IMPORTANCE OF LECTURES ON MEDICAL ETHICS.

If there is one just subject of complaint in the medical education of the present day, it is of the number of lectures the student is compelled to attend; and yet there still is a department in which he should be instructed, which is more likely to be impressed on his character by the words of his teacher than by books: we allude to MEDICAL ETHICS. There is no other profession than ours, in which its members are more frequently brought into collision with each other, in circumstances where their own interests and those of their patients are at stake, and which not only require the knowledge of what is right, as a matter of professional etiquette, but also correct principles of conduct, and tact in their application. The consequences of failure in these respects are often very severe. Many a young man throws himself back for years, or totally hinders his advancement to any high status among his brethren, by his ignorance or neglect of what is due from man to man in his early collisions with his fraternity. Those men who are born and bred in the higher classes of society get a facility of observation, a conventional sense of honour, and a knowledge of what is gentlemanlike or the reverse, from constant intercourse with gentlemen; and this training inclines them almost intuitively to do what is correct towards others, and just to themselves, in the intricate affairs of life. In short, they act as gentlemen, even although they may not be guided by the highest principles. Again, those who have been early brought up to do to others as they would have others do to them, and who have honest, simple hearts, arrive at the same results by a nobler path and a less complex method.

But the large intermediate class, who have neither had early nor high social education, nor possess the simple honesty of nature raised by religious training, learn what is right in these duties only from much blundering, from cruel mistakes, and from all the trials of an uneducated experience. To this large class, how many medical students belong, who are, when they leave the schools, to be cast upon the rough sea of life, without compasses or chart to guide them in their intercourse with society! Were they Christians in the high sense of the term, or were they thoroughly well bred, either of these disciplines would have sufficed; but, on the contrary, they have had none of that strict social training which compels them to think and to study the feelings of others, and perhaps they have never seriously considered that their success in life would greatly depend on their just, kindly, considerate, and honest treatment of their fellow men. In these respects, how many who have had a pretty good scientific education are still savages, and unable even to appreciate the value of the best manners, from an ignorance of the difficult discipline from earliest years of which they are the fruit! And thus how many medical students may be laboriously trained in the science of medicine, and yet left in ignorance of the duties which they owe as men to their patients, their fellow practitioners, their profession, and

to themselves!—a kind of knowledge which is essential to the proper practice of their art. The metropolitan teacher may watch with pleasure the scientific progress, the zeal and industry of his pupil; and may not suspect that the strong emulation he has been exciting by his prizes and praise, and the active diligence he has fostered by these encouragements, may both ere long be employed in endeavouring to get practice at all hazards, to gain success for himself, whoever is overthrown, *rem quocunque modo rem*; until he may discover that the world will not stand such conduct, when he may find himself suddenly thrown upon his back by its strong arm. Like a boy spinning a cockchafer, he never thought of the pain he was inflicting on another, he was so absorbed in himself.

Now, it is this ignorance we would wish to see reformed; and this selfishness, enlightened and corrected—this want of knowledge of what is due from one man of education to another, practising the same liberal profession, removed. Teachers who have gained the confidence and the affections of the students by superior knowledge, high character, and kindness, are their proper instructors in conduct. The influence founded on high acquirements and zeal, would give their advice in manners (*mores*) the weight of authority; and they might awaken in many a young heart a sense of duty to which it had been a stranger. The seniors of the profession have often made medical conduct the theme of introductory lectures; but though an introductory lecture affords a good opportunity for inculcating general principles, it does not afford an opportunity for going into the requisite details; and, impressed as we are with the importance of the subject, from the observation of the early course of young men in practice, we would, at this season of the year, urge on the professors and lecturers at the metropolitan schools the reasonableness of making medical ethics a part of medical education. This may be done, either by the delivery of a short course of systematic lectures, or by each professor of a practical branch devoting a few lectures to this subject, which is so closely connected with the pupil's success. Schools, which would make medical ethics a branch of medical education, would have a greater claim on parents, and on those masters who take a lively interest in their pupils' London career and subsequent well doing. Instruction in Medical Ethics might soon lay the foundation for the most solid reform in our profession—that which is based on the improvement in conduct of each of its members.

MR. SYME AND MR. HESTER.

It is doubtless fresh in the recollection of many members of the Association, that a complaint was made by Dr. Simpson, at our recent anniversary meeting, against the Association, for having published under its authority an attack upon Mr. Syme and the profession in Edinburgh.

The passage to which we refer is contained in the "Address in Surgery", delivered last year at Oxford, by Mr. Hester, of that city; and is as follows:—

"If we cast our eyes beyond the Tweed, we see the melancholy exhibition of a city, celebrated through long ages as the birth-place of genius, torn by two rival factions and a petty squabble about the perineal section. It is not in these days a question whether the operation originated with Dessault or Syme, nor whether it be adapted for the cases in which it has been recommended. The ultimate condition of the patient is lost sight of in fierce animosity and personal invective, and the two leading surgeons have appealed to a Court of Law upon a question of truth. *Proh pudor!* It were vain to expect them to issue from the contest humbler, better, and wiser men. But should their repentance be ever so great, it will never efface the scandal such proceedings bring upon the profession.

"That such scenes may shortly cease to be enacted in the modern Athens, is my most earnest prayer; and as to ourselves, may we ever be delivered from envy, hatred, malice, anger, and all such pestiferous perturbations, which militate in no small degree against that tranquillity of mind so essential to the practice of the healing art. Were we to take a retrospect of the whole of this unhappy quarrel, in which direction must we turn for liberality or courteous bearing? Where is the trace of industry or of research? It is not even clothed in sparkling wit or glowing language. No! The terms which have been selected would have better suited the tavern or the hustings. If there be value in the practice recommended, we, as independent but anxious trustees of the public health, have a right to ask for a new series of experiments, under circumstances which would admit of no misunderstanding. Until then, no violence of language, no unblushing assertion, even in the form of advertisements in the public journals, will have weight to influence our judgment."

Trusting that the decision adopted at Swansea would be deemed satisfactory, but being at the same time uncertain as to this, from the tenor of our private letters from Edinburgh, we abstained from noticing the subject when speaking, at p. 717, of the proceedings of the Swansea meeting; and now, it is not willingly, but from necessity, that we refer to so disagreeable a topic. Circumstances, however, have occurred which force us to break silence; but, in doing so, we shall keep in view the rules which we laid down for our guidance in our inaugural address published on the 7th of January.

Upon the motion of Dr. Sibson of London, seconded by Dr. Radford of Manchester, the following resolution was carried at the last anniversary meeting:—

"That the Association regrets that there should be any misunderstanding between Mr. Syme and Mr. Hester; but that the Association does not hold itself responsible for the sentiments expressed in the papers which may be published in the *Transactions*, and recommended for publication on account of their general merits."

In the opinion of Dr. Simpson, this resolution does not offer due reparation and redress for the publication of Mr. Hester's statements, which he characterises as calumnious and truthless. He thinks that the Association did not do enough when it withdrew its sanction from the passage complained of; and, under this conviction, he forwarded to us for publication a voluminous correspondence, which, for reasons explained in the following letter, we have resolved not to insert in the Journal:—

FROM DR. CORMACK TO PROFESSOR SIMPSON.

"Putney, Sep. 14, 1853.

"MY DEAR SIR,—Notwithstanding the arguments used in your recent letters, I am still of opinion that I ought not to insert in the ASSOCIATION JOURNAL the correspondence which you have transmitted to me for publication. It is my hope and my belief that the obnoxious paragraph is no longer the property of the Association, and that it was technically repudiated by the resolution adopted at Swansea. Mr. Hester must now, I think, be regarded as the sole proprietor of the paragraph.

As the Association certainly intended finally to settle this most unpleasant business, so far as they and Mr. Syme are concerned, by the decision to which I have referred, I feel that it is my duty not to open the Journal to its re-discussion. I therefore return to you the correspondence, as you intimate your intention of bringing it before the profession, even though I should decline to publish it in our Journal. The following are the letters which I return:—

- "1. Dr. Simpson to the Editor of the ASSOCIATION JOURNAL, Aug. 26, 1853.
 - "2. Dr. Simpson to Sir Charles Hastings, May 1853.
 - "3. Sir Charles Hastings to Dr. Simpson, May 20, 1853.
 - "4. Dr. Simpson to Sir Charles Hastings, May 25, 1853.
 - "5. Sir Charles Hastings to Dr. Simpson, May 31, 1853.
 - "6. Dr. Simpson to Sir Charles Hastings, June 4, 1853.
 - "7. Sir Charles Hastings to Dr. Simpson, June 7, 1853.
 - "8. Dr. Simpson to Sir Charles Hastings, June 14, 1853.
 - "9. Sir Charles Hastings to Dr. Simpson, June 23, 1853.
 - "10. Dr. Simpson to Sir Charles Hastings, July 25, 1853.
 - "11. Sir Charles Hastings to Dr. Simpson, July 27, 1853.
 - "12. Sir Charles Hastings to Dr. Simpson, August 17, 1853.
- [This letter enclosed the resolution adopted at Swansea.]

"13. Dr. Simpson to Sir Charles Hastings, August 26, 1853.

"Allow me to add that, as not a single member of our Association has adopted or defended Mr. Hester's sentiments since they appeared, and as the undoubted object of the Swansea resolution was to sever all connexion between those sentiments and the Association, you and Mr. Syme might, I think, with great propriety, allow the matter, as regards the Association, to rest where it is. In any case, I beg you will offer to Mr. Syme the expression of my high esteem, and that you will accept the same from

Yours very truly,

"JOHN ROSE CORMACK.

"To J. Y. SIMPSON, M.D., Professor of Midwifery in the University of Edinburgh."

While we close our pages against the re-discussion of Mr. Hester's paragraph, we cannot avoid expressing our extreme regret that the Association, in the twenty-second year of its existence, should still be without ethical laws for its guidance, and without a tribunal for the authoritative investigation and settlement of all cases in which members are accused of acting *contra bonos mores*.

REFORM OF THE CLUB SYSTEM.

TO-DAY we publish two admirable letters upon the Club System, a subject regarding which we propose next week to make some further remarks.

We trust that powerful committees may soon be constituted in all parts of the kingdom for the radical reform of the club system—committees similar to those which arose from our articles on gratuitous advice, and one of which is now investigating so diligently, and yet so unobtrusively, the gratis system, as it prevails within the bounds of the Metropolitan Counties Branch.

With reference to the suggestion of S. T., in favour of a five shilling semi-membership, we are not prepared to offer any decided opinion; but our present belief is, that such a project is utterly impracticable, and for this reason, that it would probably still farther increase a body of gentlemen already too numerous—those who read and applaud the Journal, and contribute nothing to its maintenance. At least, one member's copy visits weekly by post three practitioners who are not members, and who assign this accommodation as the cause of their not finding it necessary to join the Association. Again, at least four wealthy reading societies are supplied with the Journal by their secretaries (who belong to our body), giving their copies *gratuitously*, or for a consideration.

ORIGINAL COMMUNICATIONS.

ON YELLOW FEVER:

COMPRISING THE HISTORY OF THAT DISEASE, AS IT APPEARED
IN THE ISLAND OF ANTIGUA IN THE YEARS
1835, 1839, AND 1842.

By THOMAS NICHOLSON, M.D.

(Read before the Epidemiological Society of London,
July 4th, 1853.)

THE subject of the following essay is that peculiar form of fever, which, under the different names of Yellow Fever, Vomito Negro, Vomito Prieto, and Bulam Fever, has been known to the English and Spanish colonists on both sides of the Atlantic for nearly a century, occurring at distant and uncertain intervals, and producing great mortality, especially amongst Europeans who have resided but a short time in these parts. It has been described by nosologists under the terms of Typhus Icterodes, *Cullen*; Synochus Icterodes, *Young*; Epanetus Malignus Flavus, *Good*; and more recently by Dr. Copland, from its pathological characters, Hæmagastic Pestilence. The term Hæmolytic Epidemic of the Atlantic shores would, in my opinion, express more accurately the peculiar features of the disease; but I am unwilling to make any additions to its nomenclature, which, after all, is of little importance.

I had been thirteen years in Antigua, before I had an opportunity of witnessing a single case of this disease, although severe and fatal cases of bilious remittent were met with in malarious localities every year, and in some seasons prevailed as an epidemic over the whole island; as, for instance, in the year 1823, a short account of which, by my friend Dr. Musgrave, will be found in the twenty-eighth volume of the *Edinburgh Medical and Surgical Journal* for 1827. Yet, although the mortality from this epidemic was very great, in no instance did black vomit occur; and, from the best information I could collect on the subject, I have every reason to believe that vomito prieto was not known amongst civilians in that colony, from 1816 till 1835. I exclude, of course, the cases of the *Pyramus*, and two other men-of-war, which arrived at English Harbour with yellow fever in 1821 and 1822.

Being taught in my early years, by the writings of Bancroft, Fergusson, and others, and by the oral instructions of the medical gentlemen under whom I served in the West Indies, to regard yellow fever as a more severe grade only of the endemic fever, I was often puzzled to account for the absence of this peculiar symptom in all the cases I had seen; and I was sometimes inclined to hazard an opinion that, after all, Chisholm might be right. Subsequent experience has convinced me that yellow fever differs as much from bilious remittent, as the epidemic or Asiatic cholera differs from sporadic or English cholera; but I never met with any circumstance that could prove its propagation by contagion. The following history will show that it broke out in St. John's in 1835, at a time when our harbour was almost destitute of shipping, and when, consequently, we had no intercourse with the neighbouring islands; and, although convalescents were frequently carried into the country for change of air, the disease was not propagated in the rural districts.

On the 12th August, 1835, the island of Antigua was visited by a severe hurricane, which did great damage to the buildings in town and country, but more so to the vessels in the harbour of St. John's, most of which were driven on shore and destroyed, or so much disabled as to be unfit for sea. A person inexperienced in these tropical tornadoes, can scarcely form an adequate idea of the fury with which the wind raged for a few hours. The barometer fell in the course of one hour and twenty minutes 1.5 inch, a rapidity of descent which, as far as I can learn, has not been equalled in any former hurricane on record. The centre of this whirlwind moved at a steady rate in a westerly direction, being felt some hours later at each island in that course;

and, strange to say, it was scarcely felt at all forty miles to the south of Antigua. Before the occurrence of the hurricane, the inhabitants were tolerably healthy, at least they were free from any acute or febrile diseases; but the weather was dry and sultry, and dyspeptic complaints were more than usually prevalent. The excitement, however, occasioned by the hurricane, and the vigorous exertions required to repair its effects, dispelled these anomalous complaints, and, for some weeks subsequent to the gale, the number on the sick list was small. The state of the weather was not similarly ameliorated by the atmospheric commotion. The heat was greater; the wind variable, and more westerly than usual; and there were frequent showers of rain. The sea, which rose in the gale above its usual level, aided by the wind, had deposited a great quantity of marine organic matters and vegetable rubbish about the wharves and precincts of the town bounded by the harbour; and it was remarked by the inhabitants in that quarter, that the smell arising from the sea, particularly at night, was peculiarly offensive.

On the 20th September, I was called to a case of fever in a young Irishman, who resided in a house on one of the wharves, which had suffered greatly in the gale, and was then undergoing repair. It proved rather an obstinate case; the headache, gastric irritability, and rachialgia, being very severe: but it terminated favourably. When, each successive day, one or two other cases were added to my list, I began to suspect that we were about to have a visitation of some epidemic; and it is recorded in my notebook at that time as epidemic gastric fever. It is worthy of remark, that it broke out in the same locality, and much in the same way, as the "Dandy Fever", that peculiar arthritic exanthem, which I have described in vol. xxxi of the *Edin. Medical and Surgical Journal* for 1829, p. 115.

I was attacked myself on the 7th October; and during my confinement, which was only three days, the more malignant characters of the disease were developed. But it was not till the 10th October that we had a case of black vomit, when the true nature of the epidemic was discovered. It may be necessary to mention, however, that none of the medical gentlemen engaged in practice in St. John's at that time, had ever seen a case of yellow fever, otherwise the discovery might have been made earlier.

The epidemic continued to increase till the first week of November; after which it gradually declined, and by the end of December had nearly disappeared. The last death occurred on the 24th of that month, in the wife of a Moravian missionary, who arrived in the island from England on the 9th, and was attacked on the 15th. During that period, I had attended two hundred and twenty cases; of whom seventy-five were Europeans, sixty-five white Creoles, and eighty coloured persons. Of the Europeans, twelve died; of whom ten had not been in the island twelve months. None of the Creoles or native whites died; but two of the mixed race sunk under peculiar circumstances.

In June 1839, yellow fever again made its appearance, attacking only those young men who had come to the island during the interval. This epidemic was of a more open or inflammatory type than the former, and copious venesection was practised with much success.

In September 1842, another invasion of the disease took place, and continued till the middle of November, during which time I attended forty-three cases, viz.: twenty-two Europeans, twenty white Creoles, and one of the mixed race. The Europeans had only been a few years in the colony, and of these eight died; the Creoles were chiefly children, of whom three died.

On all these occasions, it is remarkable that the epidemic was confined to the town of St. John's; and, although our practice extends over twenty-eight estates, on each of which several white persons resided, who were unprotected by a former attack, none of these took the disease.

SYMPTOMS.

In private practice, the physician has few opportunities of witnessing the premonitory symptoms of fever, except

in his own person; and therefore I will only describe what I myself experienced. I got up in the morning with an unusual feeling of lassitude, and with some uneasiness in the head, and pain in the back and limbs. I had no sense of chilliness, nor was the temperature of the surface increased; but I had much thirst, and the swallowing of liquids was immediately followed by nausea and copious perspiration. The pulse was weak and variable, and much accelerated by the slightest exertion. Notwithstanding these symptoms, I continued to discharge my professional duties till 10 P.M., when the pains in the head and back became almost intolerable, the vomiting incessant, and the febrile excitement fully developed. The paroxysm continued for thirty-six hours, when it left me in a state of extreme exhaustion, with a furred tongue, which lasted for several days, and a yellow hue in the skin and conjunctivæ.

Such was the mild form in which the epidemic manifested itself in natives and persons who had been long resident in the West Indies; but in others it assumed a highly malignant character, producing a rapid dissolution of the blood, which exuded into the mucous canals, and sometimes even through the pores of the skin; and it frequently terminated in death by asthenia or coma, on the third, fifth, or seventh day.

Three varieties of this malignant type were observable. The first I shall term the *ardent*; the second, the *adynamic*; the third, the *congestive* or *appyritic*.

I. THE ARDENT form was ushered in with the usual symptoms of a febrile attack—slight rigors, or only a coldness of the extremities, headache with suffusion of the eyes, general lassitude, and pain in the back. In a few hours, these symptoms were followed by a hot burning skin, great throbbing of the carotid and temporal arteries, intense headache and rachialgia, pulse from 90 to 120, full and strong, incessant thirst, and vomiting of fluid which often exceeded in quantity what was swallowed. The bowels were obstinately constipated, the urine high coloured, and sometimes entirely suppressed. The discharges from the bowels produced by medicine, generally resembled ditch water, being free from all appearance of bile. The blood drawn at the first visit presented no unusual character. About the second day, the patient complained much of flatulency in the stomach, occasioning frequent efforts to expel it, which Dr. Dewees of Philadelphia has very graphically described as a *vomiting of wind*. There was also a sense of stricture about the cardiac orifice. On the third day, the skin had assumed a lemon colour, which was first perceptible in the conjunctivæ and upper parts of the neck; the heat had subsided, but the pulse had increased in frequency; hiccough was urgent. The matters vomited were mixed with dark flakes, sometimes resembling snuff, sometimes the dregs of port wine. Soon after this, two or three pints of a black fluid, like soot and water, were ejected with great force, and death closed the scene. In some cases, the vomiting would cease suddenly, either spontaneously or on the exhibition of an opiate, and violent delirium or coma would supervene.

CASE I. D. G., aged 21, engineer, lately arrived from England, Oct. 23, 1835, awoke with a sense of fatigue and pain in his back, which he ascribed to a long walk he had taken the evening before. At noon, he was found in a high state of fever, with intense pain over the orbits; red watery eyes; pulse 100, full and strong. He was bled to thirty ounces; and pills of calomel, compound extract of colocynth, and jalap, were ordered. The bleeding relieved the headache, reduced the pulse to 80, and occasioned a copious diaphoresis. At 4 P.M., headache and febrile heat had returned; and vomiting was urgent. The abstraction of eight ounces of blood was again followed by relief of all the symptoms. The pills were repeated every second hour, with effervescing draughts of the tartrate of soda. 8 P.M. The fever was less violent; the bowels had not been moved. The hair was cut; and cold affusion applied to the head as often as the heat returned. The medicines were continued.

24th. Headache and vomiting were still urgent; the medicine had acted but slightly. Five grains of calomel were

given every two hours, with solution of sulphate of magnesia in the intervals. A sinapism was applied to the epigastrium. The cold douche was continued.

25th. The medicines had acted slightly; and heat had abated. There was frequent emission of gas; a yellow tinge of the skin; scanty urine. A blister was applied to the epigastrium; the calomel was continued, with two grains of camphor, every two hours.

26th. He was much easier; had had dark tar-like stools.

27th. He was reported to have passed a quiet night; but I found him at 6 A.M. sinking; the skin cold, and pulse scarcely perceptible. Wine and other stimulants were prescribed; but he died at 10 A.M., immediately after ejecting a washhand-basinful of the black vomit.

POST MORTEM EXAMINATION, at 3 P.M. The external surface was of a yellow colour, spotted with purple patches.

Abdomen. The viscera appeared healthy externally. Liver of a natural size; yellow colour. The gall-bladder contained a small quantity of dark green viscid bile. The stomach contained a pint of black fluid: internal surface highly congested, from cardiac orifice to $1\frac{1}{2}$ inches from pylorus. Small intestines full of black inky fluid, which was warm, and in a state of fermentation. Peyer's glands were very conspicuous. Colon stained of a dark livid colour, interspersed with red patches. Kidneys healthy. There was half a pint of urine in the bladder.

Thorax. The pleura of left side was highly injected; on the right, old adhesions existed. No other morbid appearance was found.

CASE II. Mr. S. A., aged 25. I was called at 11 P.M. on the 8th October, 1842, to visit this young man, a native of Scotland, who had been but a short time in the island. I was informed that he had been complaining of great lassitude all day, with pain in the back and limbs. I found him labouring under intense rachialgia and incessant jactitation, with much headache and coldness of the lower extremities. His feet were immersed in hot water, and in that position he was bled to the extent of thirty ounces, with great relief to all the symptoms. His pulse, which before the bleeding was 120 and very small, became fuller, and less frequent. His skin became moist, and the temperature more equable. He was ordered to take large doses of calomel, colocynth, and jalap, every two hours till his bowels were emptied. On the morning of the 9th, Dr. Musgrave found him complaining of a return of headache, with an increase of heat, and he thought it advisable to abstract about eight ounces more blood from him. The purgative pills were continued, with the addition of a mixture of the compound powder of jalap, but his bowels were slow in responding. In the course of Monday, the 10th, his stomach became very irritable, and he brought up much larger quantities of fluid than appeared to be ingested. The prescription was a blister to the stomach, five grains of calomel every two hours, with effervescing draughts. On the morning of the 11th, he was found much cooler, and quinine was tried: but the irritability of the stomach prevented a continuance of it. Black vomit and hiccough succeeded; and he died at six o'clock in the evening.

CASE III. Mr. F. P., aged 21, an Englishman, about two years in the island, was attacked 1st November, 1842, with giddiness, and pain in the head and back. When visited, the febrile excitement was fully developed. He was bled in the erect position till approaching syncope, when profuse perspiration broke out; the heat was subdued and all the symptoms relieved. The bowels were freely opened with calomel, colocynth, and jalap. He took ten grains of nitre, with a few drops of spirit. æth. nitros., in a glass of water every two hours. On the 3rd, he was in a state of complete apyrexia. Two grains of sulphate of quinine were given, every second hour, during the day, and on the 6th he was struck off my list as perfectly cured.

CASE IV. Mrs. P., wife of the preceding, aged 20, a native of the island, but who had been some years in England for education, was attacked November 7th with all the symptoms of the prevailing epidemic, being five months advanced in pregnancy. She was bled to the extent of twenty-

four ounces, and treated in every respect like her husband; and on the 12th she was convalescent.

CASE V. Mr. W. B., Englishman, aged 25, about three months in the island, was attacked 7th November, 1842, with the usual symptoms of the ardent form of yellow fever then prevailing. He was bled to the extent of forty ounces; was purged with calomel, colocynth, and jalap, and afterwards with effervescing draughts of tartrate of soda with nitre. On the 10th he was convalescent. He took quinine for three days, after which I took my leave.

II. The ADYNAMIC form was usually met with in females and persons of a lax fibre and deficient animal vigour. It was ushered in by slight rigors, giddiness, and pain in the back, frequent sighing, and sense of oppression at the præcordia. The reaction which followed was slight; unattended with pungent heat of the skin, or strong arterial action; the pulse was small and compressible. This stage did not last more than forty-eight hours, and was followed by the stage of collapse; great prostration of strength; cold clammy sweats; feeble pulse; hiccup; vomiting of a dark grumous fluid; yellow colour of the conjunctiva; and a livid hue of the face. Hæmorrhage from the nose, mouth, anus, and vagina, followed; under which the patient sunk in a fit of syncope or æsthenia. In others the sensorium was early affected; there was a total suppression of all the secretions; the patient lay tossing about in a state of wild delirium, totally disregarding exposure of her person. Hæmorrhage took place from all the passages; the sheets were stained with blood; her hands were bloody; the eyes yellow; the arms, legs, and back spotted with vibices. The fairest of creation became an object of pity and abhorrence: and death was hailed with joy by all her attendants.

CASE VI. Mrs. W., aged 31, native of Scotland, about three years in the island, was attacked at 5 A.M., on the 10th October, 1842, with shivering, and great pain in the back, which were soon followed by symptoms of fever of a mild character, the pulse was quick and feeble, and the skin warm, but rather moist. The fever continued during that and the following day without any urgent symptom, except a distressing pain in the back. On the 12th, she was found free from fever, and a solution of sulphate of quinine was prescribed. But at 3 P.M., she was suddenly seized with vomiting, and brought up a pint of *black fluid*; after which her pulse began to fail, and symptoms of collapse occurred. At 5 P.M., she had an epileptic fit; diffusible stimulants were administered liberally; but she remained for several days in a state of extreme exhaustion. On the 13th, hiccup was added to the other bad symptoms. On the 14th, the abdomen was tympanitic, when twenty drops of oleum terebinth. were given every two hours with good effect. Next day the bowels became relaxed. The discharges consisted of bloody serum: these were restrained by tincture of opium and carbonate of ammonia. She gradually recovered.

CASE VII. Mrs. W., aged 28, a native of England, from which she had arrived only a few months. This lady's husband was a physician, holding an official situation in the colony, but was not engaged in practice. His mother-in-law died of fever on the 15th October, 1842, never having been considered by him in danger till fatal coma occurred. This unexpected event occasioned much grief to Mrs. W., and she was preparing to accept the invitation of a friend to spend some time in the country, when I was sent for. On the 25th October, I found her seated on a chair dressed in mourning, and the carriage at the door ready for the journey. She complained of giddiness, pains in the back, and a total prostration of strength. Her husband was urging her to proceed, protesting that she was suffering only from grief and want of sleep. Her pulse was quick; and there was increased heat about the head and trunk; although her skin was generally moist. I sent her to bed, and called a consultation of her medical friends in two hours; when I hoped reaction would have taken place, and as she was of a plethoric habit, though phlegmatic temperament, the propriety of bloodletting might be a question of intricacy. At our visit, fever was more fully developed; but the state of the pulse did not admit of venesection. Purgatives, into

which calomel entered largely, were prescribed, to be repeated at short intervals. Next day there was no distinct change. The following day, the febrile symptoms were increased, with much cerebral excitement and constant jactitation. The head was shaven; and calomel with camphor, were given twice every two hours. But the symptoms became gradually worse. The delirium was violent, and she was with difficulty retained in the bed. The secretion of urine was suppressed; hæmorrhage took place from the nose, mouth, and vagina; the skin was yellow, and the arms, legs, and depending parts were marked with livid spots. She died on the fifth day. Her husband was attacked with the disease under the congestive form on the 27th, and died on the seventh day.

III. The CONGESTIVE form is characterised by the total absence of febrile heat. The patient has a stupid, drunken appearance, will scarcely admit that he is ill, or complains only of slight pain in the back and limbs. He staggers in his gait, or lies in a soporose state. Deafness ensues, and afterwards low muttering delirium. The pulse is at first slow and intermitting; it becomes quicker in the progress of the disease, but seldom exceeds 100. The stools are unnatural, without any admixture of bile; the urine is scanty, and is ultimately suppressed. The skin is of a yellow mottled hue. Hiccup occurs early, with black vomiting, and hæmorrhage from the mouth and nose. The case usually terminates by convulsions or coma.

CASE VIII. Mr. F., a native of the United States, aged 38, about a week after his arrival in Antigua, in November 1835, was attacked with slight headache, and pain in the limbs, which he said he would scarcely have noticed but for the prevalence of yellow fever in St. John's. His pulse was slow and intermitting. His medical attendant treated him with active doses of calomel; but the bowels were scarcely moved, and the discharges were destitute of bile. On the third day he became tinged with a yellow suffusion. On the fourth I saw him; his pulse was then 96; he had hiccup; hæmorrhage from the gums; and vomiting of a brownish fluid with dark coloured flocculi. The urinary secretion was suppressed. Being a stranger, and a man of family, the merchant to whom he was consigned, requested that we would make known to him our opinion if we thought him in danger. This was done in as considerate terms as possible by his medical attendant; when he replied very angrily, that he begged leave to differ from us, he was not ill, and we had quite mistaken his complaint. Next morning he was found incoherent, sitting up in bed and with a fixed melancholy gaze and corrugated brow: blood was issuing from the pores of the right cheek. He took no notice of us as we entered his room, but continued repeating the letters of the alphabet slowly. He died in the evening, after several convulsions.

DISSECTION. On opening the abdomen, the stomach was observed much distended, and presenting on its external aspect several dark spots like incipient gangrene; but on laying it open, this was found to be occasioned by the abrasion of the mucous coat in several places, and the presence of a black inky fluid, like soot and water. The mucous membrane of the upper half of the duodenum was also abraded. The rest of the intestines were sound. The liver was pale; the gall bladder was distended with dark green bile. The lining membrane of the heart was highly injected and studded with patches of extravasated blood on several places. The sigmoid valves exhibited the same appearance.

ANATOMICAL CHARACTERS.

The yellow colour of the surface of the body was always more distinctly visible after death; and on the depending parts it was mixed with purple patches. All the appearances indicated a defective crisis of the blood: it remained fluid after death. The capillaries of the serous membrane were in a state of hyperæmia, but there was seldom any exudation of *liquor sanguinis* perceptible. The mucous membrane of the upper half of the alimentary canal was generally softened, and the epithelium detached from the stomach and duodenum. The muciparous glands were found enlarged only in one

case. The stomach contained always more or less blood, which was changed into a black colour, and frequently mixed with gas. The liver was usually of a pale bloodless colour, and the spleen presented no unusual appearance. The gall bladder was sometimes tinged with black bile, in other cases it was nearly empty. The thoracic viscera exhibited only such appearances of congestion as were referrible to the fluid state of the blood, and the mode of death. In one case, the blood in the right ventricle had a frothy appearance, having been evidently mixed with gas during life.

DIAGNOSIS.

The only diseases with which yellow fever can be confounded are bilious remittent, and the malignant forms of intermittent fever, and as many medical men, for whose opinion I entertain the highest respect, consider all these fevers as the offspring of the same terrestrial miasmata, modified only by the constitution of the individual, and other unknown agents, it is necessary that I should relate more fully the circumstances which have induced me to form a different opinion. My experience is derived entirely from a residence of twenty-five years in Antigua, where intermittent and remittent fevers are endemic, and met with every year, chiefly from September to March, and where yellow fever has only occurred three times during that period. The endemic fevers prevail chiefly in the country districts, and the inhabitants of St. John's are seldom attacked with them. Whereas, the epidemic yellow fever was confined to the city and the garrison at the Ridge, and English harbour. It is difficult to account for the comparative exemption from remittent fever which is enjoyed by the European youths who are employed in the mercantile profession in town, whilst those who superintend agricultural operations in the country, never escape.

Antigua is of a rough circular figure, being 20 miles long and 54 in circumference, containing 108 square miles, equivalent to 69,277 acres; two-thirds of which are under cultivation. There are few springs in the island, and no streams that deserve the name of rivers; but it is much indented with creeks and bays, whose oozy waters maintain the growth of impenetrable thickets of the different species of mangrove, and are the fertile sources of malaria.

In a geological point of view, the island comprises three distinct formations of the tertiary class, of which the most superficial beds occupy the northern and eastern divisions. These consist of a calcareous marl, and coarse sandstone, interspersed with masses of a tolerably compact shell limestone. On the surface are found a great variety of marine exuvise, analogous to those which at present inhabit the surrounding seas, as *astrea*, *meandrina*, *tubipora*, etc. The surface of this district is exceedingly broken and undulated, consisting of a series of round backed hills of no great elevation, covered with a light arid soil. The sides of the hills and intervening valleys are highly cultivated, and produce a rapid growth when duly favoured with rain.

The mountainous district, forming the southern and western divisions, is composed of rocks of the newest flötz trap formations, as *wacke*, *porphyry*, *trap breccia*, *amygdaloid*, and some spherical masses of basaltic green-stone. Some of these mountains rise with conical summits to the height of 800 or 1,000 feet; others, of the same elevation, are more rounded and less precipitous, affording a good soil for the sugar-cane even on the tops. They are intersected by beautifully romantic valleys; and the abrupt sides of the mountains are clothed with the verdant foliage of a great variety of herbs, and trees, and twining shrubs.

The immediate district is occupied by a series of argillaceous strata of varied characters, which dip at a considerable angle to the north and north-east, and extend across the island from Willoughby Bay to St. John's. The northern limit of this district is formed by a zone of low land, which, at no very distant period, appears to have been submerged, and even now, after heavy rains, is readily converted into a marsh. It rises with a gentle declivity towards the south and south-west, when it presents a precipitous escarpment, and is divided from the truss formation

by a ravine, in which are pools of stagnant water, and a sluggish stream, which runs towards the west, through a beautifully luxuriant plain.

Although this district, and the many lone creeks with which the island is indented, present the only unequivocal sources of paludal emanations; yet all parts of the island are at certain seasons affected by malaria—the dry, calcareous soil of the north, equally with the humid valleys of the south. How is this to be explained? Two things are always present when fever prevails in these districts—a hot sun during the day, and circumstances favourable to the radiation of heat from the earth, and the deposition of dew at night.

The febrile poison, whatever it may be, appears to be deposited with the dew, even at a distance from its source; and all who are subjected to its influence, as it rises again at the approach of the sun, are as much affected as if they had inhaled it at the fountain-head. This is the only way in which I can explain the greater prevalence of fever in country districts than in St. John's; it being well known that more dew is deposited in the open country than in cities, where houses conceal a portion of the sky. A soil covered with vegetation is also more favourable to the production of dew, than the trodden streets of a town. At these seasons, the mean dew point is upwards of 70°; and, in the cloudless moonlight nights, the thermometer falls sometimes to 66°, producing an unpleasant sensation of cold, of which the inhabitants of northern latitudes, who enjoy a temperature some degrees lower than this, can scarcely form an idea. The injurious effects of dew have been long known to the vulgar; and I think it has been unjustly overlooked by the late Dr. William Fergusson, in his interesting paper on "Marsh Poison".

So much for the extrinsic cause of endemic fevers. Let us next inquire whether these fevers may be so far modified by constitutional peculiarities in the European, as to assume the *continued* or *malignant* form of yellow fever. Since the year 1837, a considerable number of English labourers have been imported into Antigua, which has afforded me an opportunity of seeing this question put to the test of experiment; and, although they have all suffered more or less from the *fièvre du pays*, not one case of black vomit has come to my knowledge. In May 1843, twenty-six English tradesmen were imported, by a wealthy mercantile firm, for the purpose of rebuilding those works which were destroyed by the earthquake on the 8th of February of that year. They were lodged in the country, in a house sufficiently roomy, and in every respect commodious, but in a locality much exposed to malaria. Their employer, considering the heat of the sun the only thing likely to be prejudicial to the health of these unacclimated strangers, allowed them to retire to their house for three hours at noon; but they entered on their work before sunrise in the morning. They were all attacked in a short time with remittent fever, of the most aggravated type, attended with a deep yellow colour of the surface, delirium, etc.; yet they all recovered without hæmorrhage from the mucous passages, black vomit, or any symptom indicative of that dyscrasia of the blood peculiar to yellow fever.*

Again, in 1845, about thirty mechanics were imported, to rebuild our cathedral, which was destroyed by the same visitation. They were located in St. John's, where they remained upwards of two years; and not one of them was attacked with fever—another proof of the greater prevalence of the endemic in the country than in town, and also that an unseasoned constitution is not sufficient to convert remittent into the continued yellow fever.

I am desirous of confining my remarks to what came under my own observation, otherwise I might add, that yellow fever occurs where marsh fevers are not known, as on board of ships at sea, in the garrison at Barbadoes, Vera Cruz, etc.

* One old man died afterwards in the Colonial Infirmary, of the fever; and I have heard that some of the others died of dysentery on the passage to England, no doubt from organic changes in the viscera produced by the fever.

Are there no symptoms by which yellow fever may be distinguished from other forms of tropical fever? At the commencement of this disease, there are no symptoms by which it can be distinguished from an attack of the endemic, or even any other ephemeral fever arising from atmospheric changes. The suffusion of the eyes, pain in the head and back, closely resemble the precursory symptoms of influenza. It is only in the progress of the disease, when the torpid state of the secretory glands, the chlorotic hue of the skin, and hæmorrhage from the mucous surfaces, reveal the nature of the epidemic. Whether the morbid state of the blood, which forms the *pathognostic* symptom of this fever, is the immediate effect of its contamination with a poisonous principle from *without*, or merely the consequence of defective elimination of effete matter generated *within* the body, is a question that has not yet been determined. Probably this change in the vital fluid is attributable to both causes.

It is very evident that the first link in the concatenation of morbid phenomena is congestion of the capillaries of the brain, spinal cord, and abdominal viscera; and the great benefit derived from blood-letting at the commencement of the attack, so as to remove this state of congestion, would seem to prove that it is the chief proximate cause of the disease. On the other hand, the great susceptibility of Europeans, who have never had the disease, and the immunity of those who have once had it, and of those whose blood has been modified by a long residence in a warm climate, look like the operations of a morbid poison on certain substances, which may exist in the blood of one individual, and not in another.

The yellow colour which attends bilious remittent is generally, if not always, produced by excessive secretion of bile, and the reabsorption of some of it into the blood: notwithstanding, a large quantity is duly excreted, as shown by the colour of the stools, which varies from a deep yellow to a dark green. Some doubts have been entertained recently whether excretions from the bowels of a green colour are due to bile; but of this no practitioner in the West Indies can possibly have any doubt.

Louis, in his observations on the yellow fever of Gibraltar, has laid much stress on a peculiar colour of the liver, as a diagnostic character. Nothing very remarkable to the naked eye was observed in the Antigua fever, except in some cases its anæmic colour; and we had no means of making a microscopic examination.

Not the least remarkable feature in the history of yellow fever is the fact generally admitted, that it attacks an individual only once in his lifetime. This was in great measure corroborated by the epidemics that fell under my notice; not one of those persons who suffered in the first epidemic was attacked in the subsequent visitations.

TREATMENT.

When the epidemic began in 1835, it was treated on the general principles pursued in the treatment of fevers within the tropics. At the first visit, if the symptoms were sufficiently urgent, and particularly if the patient was a European, in whom the tone of the vascular system was increased, blood was drawn in sufficient quantity to produce a decided impression on the system, as indicated by relief of the headache and pain in the back, reduction of the pulse, and a general diaphoresis; an active purgative of calomel, compound extract of colocynth, and jalap, was administered, and repeated every two or three hours, till a satisfactory discharge from the bowels was produced; the action of the kidneys was stimulated by small doses of nitre, frequently repeated; and the head and chest were assiduously sponged with cold water. When these measures failed to relieve the febrile symptoms, and to rouse the liver to increased secretion, five grains of calomel were given every two hours. Vomiting was arrested by the application of rubefacients of capsicum or mustard, or sometimes of a blister to the epigastrium, aided with saline effluents, or a draught of magnesia, tincture of opium, and mint water.

The following case, however, created a strong prejudice against blood-letting. Calomel was given in some cases to the extent of 250 grs., without any sensible effect on the system; and it could generally be detected at the bottom of the vessel containing the watery stools, in the form of black oxide.

CASE IX. Mrs. B., a native of England, aged 35, was attacked, on October 4th, 1835, with symptoms of the prevailing fever. Her husband, in his youth, had been some time in an apothecary's shop, and still retained a love for the profession, which he displayed occasionally by the practice of minor surgical operations, such as bleeding and extraction of teeth, for the benefit of his friends. On the evening of the 4th, he made various ineffectual attempts to draw blood from Mrs. B.; and on the 5th I was sent for. I found her labouring under symptoms of a mild attack of the fever, and venesection might have been considered unnecessary; but, to please her husband, and at the same time, perhaps, not a little influenced by a desire of convincing him that he was not an expert surgeon, I abstracted about sixteen ounces of blood at a full stream. This depletion appeared to be well borne, and the headache and other febrile symptoms were much relieved. She had already taken purgative medicine, and a mild febrifuge was all that was considered necessary. Her husband was attacked the following day, and I myself on the 7th, having left Mrs. B. apparently convalescent. On the morning of the 9th, she was so well, that she got up, and went into the adjoining bedroom, where Mr. B. was lying. She sat for some time on his bed, endeavouring to comfort him with religious conversation, and expressing her gratitude that she had so far recovered as to be able to attend to him. On returning to her chamber, she discovered that she had a discharge which she took for the catamenia. Soon afterwards, she was attacked with syncope. Messengers were sent in every direction for medical men, and three were very soon at her bedside; but the vital spark had fled. Two of these medical men were strongly opposed to the use of the lancet in fever, and it was very currently reported that Mrs. B. had fallen a victim to this rash practice; and the effect on the public mind was such, that to propose such a measure afterwards was met with horror both by the patient and his friends.

The lancet was not used in any of the cases that died subsequently, except that of D. G., already described.

In the epidemic of 1839, when the ardent form prevailed, and also in 1842, blood-letting was had recourse to at the commencement of the attack, with great benefit, and, in some cases, to a very large extent.

Our assistant, Dr. C., lost about sixty ounces of blood, and my son not much less; and, in a few days, they were both convalescent. However, it is only within the first twelve hours from the commencement of the hot stage, that this bold treatment is admissible. If the congestion in the capillary system is not removed by the early and decided use of the lancet, the blood soon becomes so disorganised, and the tone of the extreme vessels so destroyed, that the loss of even a few ounces cannot be borne with safety.

CASE X. Mr. C., aged 23, a native of England, had been about six weeks in the island, when he was attacked with symptoms of yellow fever, on the 8th October, 1842. He had been confined to his bed, and under treatment for a sprained ankle, for some days previously; so that the first twelve hours of the fever were overlooked. On the morning of the 9th, he was bled; but a tendency to syncope occurred before eight ounces of blood had flowed. His pulse was never above 90. On the 10th, he had black vomit, and the stage of collapse commenced. His skin was yellow, and mottled with livid spots. Wine and porter were given liberally, and for a time he appeared to be recovering his strength; but, on the evening of the 11th, the wound in his arm burst out bleeding, which was not observed till his pulse was nearly extinguished. He died at midnight.

In the *asthenic* form, blood-letting was of course never thought of; and in the *congestive*, I never had the courage to make the trial. In the latter moments, diffusible stimulants, rubefacients, and blisters, were the remedies used;

but they were generally as ineffectual as if they had been applied to a dead body.

During convalescence, quinine was always administered, to the extent of six or eight grains of the disulphate daily; and the dietetic regimen required the utmost attention.

The foregoing essay was written in the early part of 1849, and presented to the Faculty of Medicine in the University of Glasgow, as a graduation thesis. On my return to Antigua in November of that year, I found that yellow fever was prevailing amongst the European troops to a most fatal extent; the surgeon and many of the men of the 54th Regiment having fallen victims. On this occasion, it was remarkable that the civilians, unconnected with the garrison, were entirely exempt from the epidemic. Indeed, the poisonous atmosphere appeared to be confined within very small limits, being confined to the Ridge, the chief military station, situated on the south-east part of the island, on a hill of 800 or 900 feet elevation, bounded by the sea on the east and south, and overlooking English Harbour and the Dockyard on the west. The northern boundary is occupied by an extensive tract of uncultivated land, covered with thickets of brushwood. After a time, the troops were removed, and placed under tents at Monk's Hill, an old military post about four miles to the westward of the Ridge, and about the same elevation. It presents an abrupt precipice to the south, which shows it to be composed chiefly of trap breccia and conglomerate, capped by a stratified rock of a beautiful sea-green colour, containing crystals of angite and other minerals.* Here the disease gradually abated; but it was some weeks before the poison imbibed at the Ridge was entirely eliminated from the system, as cases occurred among the men daily for some time after their removal. One officer, who was on a visit to a gentleman in the neighbourhood of St. John's, fell under our care. He was bled by my son at the very onset of the attack, and treated with active mercurial purgatives and saline refrigerants and diuretics. On the third day he was convalescent, and taking quinine; the only symptom of disease remaining being a remarkably slow pulse. Another officer, a young Irishman of gigantic stature and robust frame, was seized whilst on duty at Monk's Hill. Having witnessed the speedy recovery of his comrade, he was most anxious to come to town to be placed under our care. At length the colonel yielded to his wishes, and he was conveyed in a four-wheeled carriage, accompanied by an assistant surgeon.

When I saw him, it was too late for general bleeding; but his intense headache, ferret-like eyes, and bounding pulse, induced me to have him cupped on the nape of the neck. This produced apparent relief; but the case was attended from the first with an obstinate diarrhoea, which resisted the use of calomel and opium, acetate of lead, and similar remedies. Nevertheless, he survived the critical days on which death usually occurs, and we began to entertain hopes that he might struggle through it, when suddenly he was attacked with delirium, the stools assumed the colour and appearance of black vomit, and he died on the ninth day.

A melancholy case occurred in the family of an engineer officer, who was about to return to England in the next steamer. He fled to St. John's with his wife and daughter, a young lady in the full bloom of health and beauty. A day or two after her arrival in the city, this young lady was attacked with the disease, and died on the fifth day.

Five artillerymen were removed to the barrack in St. John's on the 30th November. Next day two of them sickened; and the following day the three others. They were under the care of my friend Dr. Furlonge, who has published an account of them in the *Lancet* for 1850. One died on the fifth, and another on the seventh day; the rest recovered.

I have heard much during the last three years of the

successful treatment of yellow fever in Demarara by large doses of quinine and calomel; twenty-four grains of the former and twenty grains of the latter being the usual dose. This practice is so contrary to what I consider the rational treatment of ardent fevers, that I could not in my conscience adopt it in such cases. I might venture to try it in the congestive form of the disease; and perhaps that is the type most prevalent in the swampy colonies of Guiana.

Dr. Blair has had ample opportunities recently of testing the efficacy of this empirical treatment; and the profession may justly claim from him a report of his extended experience. It is to be hoped, also, that he will publish the result of another experiment he has been making, with the view of protecting individuals from the disease by administering belladonna as a prophylactic.

[From the length of Dr. Nicholson's paper, we have been obliged to omit some of the concluding paragraphs, which, however, did not specially refer to yellow fever. EDITOR.]

ON THE ARSENICAL TREATMENT OF CASES OF SNAKE-BITE.

By BENJAMIN TRAVERS, Jun., Esq., F.R.S.

IN the ASSOCIATION JOURNAL of the 2nd instant (p. 773), I read a communication on the subject of "Snake-Bite" which is not without interest, although it contains nothing materially in advance of several suggestions which had been previously offered in reference to the treatment of these cases.

I am familiar with the effects of the "adder's bite", having witnessed the successful treatment of two cases at St. Thomas's Hospital. They were both marked by rapid and diffused swelling from the wrist to the shoulder, such as I would call *acute oedema-tension* with a dull mottled or slightly livid hue, as contradistinguished from erysipelatous redness. In both cases to which I allude brandy and ammonia were very liberally administered; and the parts were kept constantly and thickly smeared with warm oil. In one of the patients, a young man, who was brought from the vicinity of Dulwich or Norwood, the depression of the nervous system was well marked for many hours: he was very sick, and drowsy almost to torpor, with a small, jerking pulse. There was little or no complaint of pain, but pressure or handling the part produced great distress. Very simple measures were adopted for the prompt relief of the bowels by injection. I am sorry that I am unable now to speak more in detail of these cases; but I retain a lively impression of the particulars to which I have alluded. Some years ago, a case of this description terminated fatally at St. Bartholomew's Hospital; and such of your readers as are conversant with the literature of our profession, will remember the interesting narrative of Sir Everard Home, of the fatal consequence of the bite of a rattlesnake, detailed in the *Philosophical Transactions* for 1830, and the later and equally fatal example of this accident, which occurred at the Gardens in the Regent's Park.

This subject has always been one of especial interest to me, in consequence of the great probability that we possess in arsenic a remedy which, if administered boldly and in time, will rescue the sufferer from an imminent and painful death. I believe no one has ever questioned the accuracy of the facts recorded of the comparatively certain operation of the Tanjore pill, and Mr. Ireland's cases, of which he enumerates five treated with unvarying success, are powerfully corroborative of Dr. Russell's statements. Mr. Ireland, on his arrival in the island of St. Lucie, having previously heard the facts concerning the efficacy of arsenic stated in Mr. Chevalier's lectures, proceeded at once to test the truth of the proposition, by administering one grain doses of the mineral (in the form of arsenite of potash, as it exists in Fowler's solution), every half hour until the patient began to revive. He treated five cases with perfect success.

* This rock was mistaken by Dr. Chisholm many years ago for an ore of copper, and formed the basis of his theory of fish poison.—*Edin. Med. and Surg. Journal*, vol. iv, p. 393.

in this manner. The men severally took six, seven, and eight doses of the following form, before the irritating operation of the arsenic began to show itself by vomiting and purging. What is very remarkable, is the immediate and complete recovery of these patients, without the arsenic having produced any trace of its poisonous agency, or any subsequent ill consequences. Mr. Ireland prescribed as follows—

R. Liquor. arsenicalis 3ij.
Tincturæ opii gtt. x.
Aqueæ menthæ pip. ʒiiss.

to which was added half an ounce of lime-juice: the medicine being taken in a state of slight effervescence. The embrocations and clysters mentioned by him, cannot be regarded as having had much to do with the cure, but were no doubt useful in some degree.* On one occasion only did Mr. Ireland amputate the finger on account of the extent of the laceration. In the remaining instances he contented himself with paring the edges of the wound and dressing it superficially.

It is well admitted by most physicians that arsenic will cure chorea, if given in proper doses and for a sufficient time. Mr. Martin, of Reigate, and Mr. Salter, of Poole, have adduced abundant evidence of the great powers of arsenic in the cure of this disorder. Now, having a due regard to the condition of the nervous system in these two instances of its disturbance from such different causes, I think we must conclude that arsenic operates specifically and powerfully in that direction. Dr. Taylor tells us that it is not a corrosive poison, and although four or five grains have been found sufficient to destroy life, patients have recovered after taking sixty. Such a case is upon record; it was published by Dr. Roget. A grain of arsenic every half hour sounds somewhat heroically, but I should like to see this remedy tried in hydrophobia as Mr. Ireland used it to quell the effects of the snake poison. I think it may be shown that arsenic powerfully and specifically stimulates the semilunar ganglion and its tributaries presiding over the organic life of our bodies. Its "evacuant" operation is an incident of prime importance in cases of poison. It should always be given on these occasions until the patient vomits and purges abundantly.

I thank Dr. Powell for his valuable contribution to the Journal; but I fear he must assume or prove something in addition to the altered quality of the blood, before he will successfully explain the *modus operandi*, variable as it is known to be, of these subtle poisons. The nerves have their own extrinsic and peculiar properties and functions as well as the blood, and where their independent action is slighted or forgotten in the treatment of constitutional disorders growing out of local irritation, whether chronic or acute, grave errors of treatment will occur, and the practitioner's reputation will in such circumstances not always pass unscathed.

London, 8, Dover Street, September 6th, 1853.

CASE OF LARGE STRANGULATED INGUINAL HERNIA FATAL AFTER OPERATION.

By JOSEPH HINTON, Esq., M.R.C.S.

UNSUCCESSFUL cases, however unsatisfactory they may appear, often furnish us with a deeper insight into the disease, and hence I am induced to lay before the readers of this Journal the brief details of the following case.

CASE. W. H., aged about 45, a blacksmith, requested my assistance in May last. He had been for many years the subject of right inguinal hernia, which was irreducible; at various times he had while at work felt a fresh protrusion, with increase of volume in the tumour, and these attacks had generally been attended with severe pain, vomiting, etc. On these occasions, he had generally been able to restore the parts to their original size, that of a large foetal

head, by his own efforts. His habits of life had been very irregular, which his appearance bore out. On the morning in question, while at work, he felt a sudden increase of volume in the tumour, was soon suffering, and almost immediately vomited; he found that the hernia was nearly double its usual size, and it resisted all his efforts to replace it. I found that it occupied the whole of the scrotum, the penis (B) being nearly obliterated; in length, it could not have measured less than ten inches, whilst in circumference it must have been considerably greater, the neck being from three to four inches across; the whole tumour was tense, and somewhat reddish, especially at the lower portion, where there appeared, as it were, a second somewhat flattened swelling (A), the skin of which was glossy, and where there was also an indistinct feeling of fluctuation. I have endeavoured in the accompanying sketch to convey some idea of its size and appearance.

The abdomen itself was comparatively small, though rather tense; it was certainly flattened, but there was no tenderness on pressure; the parietes were loaded with fat.

During the day and the morning of that following, various efforts were made at reduction; but the careful employment of the taxis, cold applications, inclining the body on a board the lower part of the pelvis being elevated above the rest of the body, were alike unavailing. Opium in full doses checked the vomiting; several injections were given, but they produced no effect. Although in these old cases, there may be, as a general rule, less danger in delay, yet considering that he remained *in statu quo*, and that his general appearance became more anxious, I did not consider myself justified in postponing the operation. Accordingly, on the evening of the second day, he was placed under the influence of chloroform, and a last trial of the taxis in that condition proving unsuccessful, the operation was at once undertaken. My original intention was to have relieved the stricture without opening the sac; in this, I failed, not because this was within the sac, but because trusting to books, I was misled. The incision made (C) was about three inches in length, an equal portion being on either side of the neck of the hernia; the dissection was carried through a layer of fat, about three quarters of an inch in depth, until I arrived at a layer of membrane, which appeared like the sac, but which showed the bluish character which books assign to this membrane only in a very small portion; taking, therefore, a portion of this surface, which was dis-

* The very interesting narrative from which the foregoing facts are quoted will abundantly repay perusal. It occurs at p. 136 of the second volume of the *Med.-Chir. Transactions*, published in 1811.

tinctly white, I made a very small opening in it, which was immediately filled up by a substance like fat; the opening further enlarged, proved this to be omentum; and from the sac thus opened, a large quantity of bloody serum speedily flowed. The contents of the hernial sac were in front of the large intestine, immediately behind which were from six to eight inches of small intestine, evidently the recent addition to the contents of the sac, and that also which had suffered most, for it was very dark; after the division of the stricture, this was replaced, and the large intestine, which had contracted adhesions to the sac, was not meddled with. Owing to the dilated state of the large intestine, the external parts were with difficulty brought into apposition; warm water dressing with pad and bandages were applied. The patient expressed himself as being relieved, but he never appeared to rally, and gradually sinking, died in about ten hours; a slight action of the bowels previously taking place.

Twenty-four hours after death, the whole of the scrotum was of a dark purple colour, and was also emphysematous: there was no attempt at adhesion; recent peritoneal inflammation existed more or less over the whole of the intestines; the strangulated portion was less dark than at the time of the operation. The sac contained the greater portion of the colon, and apparently all the omentum, which was very firmly attached to the lower portion of the scrotum.

I merely place this case on record, as a proof that old herniæ of large size will not always admit of delay, for this had scarcely been strangulated thirty hours; and also as a caution to others, who, like myself, have not had many opportunities of *closely inspecting* the operation—I say *closely*, for it is one of those where students are very rarely able to notice the actual steps, although they may very frequently witness the cases—that we cannot always rely on the blue colour as a mark of our arrival at the sac; indeed, I should apprehend that whenever omentum is immediately beneath the sac, the blue colour cannot possibly be present, unless the latter contains so large an amount of fluid as to separate the one from the other.

Blaina Iron Works, Monmouthshire, Sept. 1853.

BIBLIOGRAPHICAL NOTICES.

COMMENTARIES ON THE SURGERY OF THE WAR IN PORTUGAL, SPAIN, FRANCE, AND THE NETHERLANDS, from the Battle of Roliça in 1808 to that of Waterloo in 1815, etc. Revised to 1853, by G. J. GUTHRIE, F.R.S. Fifth edition. London: 1853.

MR. GUTHRIE occupies, deservedly, a prominent place in surgery; and among military surgeons he stands second to none. During the Peninsular campaigns, he did good service to his country in the field; and many results of this experience will be of value to his profession in all time coming. His sphere of observation was large and varied. To the task of observing, he brought the natural gift, flanked by intelligence and activity: he has since had ample time and opportunity for reflection and thought—for leisurely digesting at home, as it were, the ingesta which had been hastily taken in the camp; and the result is now before us, in the form of condensed "Commentaries on the Surgery of the War".

A systematic review of such a work would require a regular and sustained campaign, incompatible with the time and space at our disposal. We can attempt nothing more than a mere skirmish, or affair of outposts. Campaign, we say; for we cannot in all points agree with our author; and some of the positions, which evidently he deems among his strongest, we think we could "turn", and occupy against him. On the whole, however, we have much pleasure in stating our conviction that the work is an excellent one, creditable to Mr. Guthrie, and valuable to the profession of which he is a distinguished and important member.

A favourite subject with our author, evidently, is the *treatment of wounded arteries*; and his main effort, practically, is to enforce the maxim of always doubly ligaturing the vessel at the injured part, in preference to treatment applied on the cardiac aspect, and at a distance. No doubt this is sound; and the service done in enforcing this is great and good: yet, like most sanguine men, paternally related to any good thing, Mr. Guthrie, in our humble opinion, is apt to push his favourite law a little too far, and to judge rather harshly of his brethren who sometimes venture to differ from him in practice. To the rule in question, he will admit of only one exception, namely, when ligature of the wounded part is impracticable. That few will dispute; all the more, as it seems to amount pretty nearly to a truism. But we think there is room for one other exception, namely, that it is not expedient to attempt to tie the vessel at the wounded part when that part cannot reasonably be expected to hold the ligature—being, along with the other tissues around, in a state of ulcerative and unhealthy inflammation—at the end of three, four, six, eight, ten, or twenty days, after the injury, as the case may be. Instead of placing a ligature on such a part, whence it must prematurely come away, and infallibly be followed by hæmorrhage, it is surely better to tie a healthy portion on the cardiac side, with or without moderate pressure on the ulcerating wound.

Again, Mr. Guthrie, in treating of the means whereby bleeding is spontaneously arrested in arteries, is anxious to impress upon his readers the fact that the object is accomplished mainly, if not solely, by the artery's "own intrinsic powers", namely, contraction, and the internal clot, irrespective of all supposed aid from the vacant space in the sheath, and the formation of external coagulum; at least, in "arteries of moderate dimensions, such as the middle part of the femoral or the axillary, etc." And yet, at page 206, we read of a French femoral artery divided, high up in the thigh, by a cannon shot, at Salamanca, in which the following appearances were found "on the morrow"; the man having "died exhausted, but not from any immediate bleeding, which, when once stopped, had not recurred". "The external coagulum filled up the ragged end of the artery, and was slightly compressed within by the contraction, which kept it in its place. The rest of the coagulum filled the hollow in the surrounding parts, which the retraction of the artery had occasioned. . . . Contraction had begun, but had done nothing essential." And in another case (same page), we are told, "a slight contraction had taken place, but not sufficient to have been of the slightest utility in suppressing the bleeding, which was in fact prevented by an external coagulum". Surely there is no such great difference between the femoral "at its middle" and the same vessel "high up the thigh", as to size, structure, function, or ought else, as necessitates any very marked difference in the spontaneous means whereby bleeding is arrested after transverse section. Therefore, we incline to think that here our author's faithful accuracy of observation in individual cases militates against, and is superior to, his general sweeping conclusions; and we pronounce in favour of the vacant sheath with its external clot, as generally available, with other means, for the arrest of arterial bleeding.

Once more,—Another "great principle" is, "that no operation ought to be performed on a wounded artery unless it bleeds"—at the time, is meant. This, too, seems rather sweeping. Take the following case in illustration—the very one (page 213) which Mr. Guthrie calls "the model on which the treatment of all such injuries should be founded". The man was wounded by a musket ball in the thigh. Several days afterwards, a bleeding took place, and "half filled a large pewter basin". A tourniquet was put on; and next day, the man being laid on the operating table, Mr. Guthrie tried to bring on the bleeding, but it would not come. "The man was replaced in bed, and a loose precautionary tourniquet applied. At night, the wound bled smartly again, and the blood was evidently arterial. It was soon arrested by pressure. The next day,

placed him on the operating table again, but the artery would not bleed. This occurred a third time, and with the same result." Other bleedings took place, but were restrained by pressure; and at last the hæmorrhage ceased without further interference, and the man recovered. In the hands of other surgeons, this artery would not have escaped ligature on the ground of "not bleeding". Although it obstinately refused to bleed exactly at the time wanted, as if instinctively aware of Mr. Guthrie's peculiarity, and wishful to escape his knife and needle; yet it bled quietly, by itself, shortly before and shortly after; and should have been held a "bleeding" vessel—to be tied accordingly.

But a truce to our "skirmishing". On looking at the whole performance with a reviewing eye, we are quite satisfied; and we find special cause to commend the praiseworthy pains which Mr. Guthrie takes to keep himself on a level with the progress of his profession, taking as kindly to the microscope and stethoscope, as if they had been born with him; and, though very "pure" in his surgery, scorning no aid which science can afford. In this particular he contrasts very favourably with smaller surgeons we wot of; and he thus reads them a lesson, from which, ere long, we hope to see them profit.

Many of Mr. Guthrie's cases are of historical interest; concerning, as they do, men well known to fame, and dear to their country's remembrance. Often, too, characteristic traits of the British soldier are freshly and pleasingly exhibited. For instance, at Campo Mayor (p. 540) a lieutenant of dragoons is shot in the body. He felt "a terrible shock", but did not fall; and, looking down, found his bowels protruding in front, while copious bleeding was taking place behind. A French officer called out "Rendez vous, mon officier!" But the dragoon replied "Pas encore, monsieur", and rode away with his bowel in his hand. The *esprit* here is really delightful; and we rejoice to learn that the gallant fellow ultimately recovered. But, in the next edition, we would fain see some other "characteristics" of reckless soldiering prudently omitted. At page 457, for example, one does not read the profane doggerel of Colonel D—, without a double regret—that a brave soldier should have been capable of such sorry things, and that a skilful surgeon should have blotted his good book by their transcription.

We care not to throw aside our pen, without saying one word on a subject at present of great importance—the establishment of a metropolitan Chair of Military Surgery. The necessities of the time call loudly for such an institution—but let its duties be wisely arranged. To make the course one of general surgery with but a military rubric can be productive, in our opinion, of nothing but injury—to general surgery and to military surgery alike. We would have the course specially limited and defined, as something in harmony with, and dependent on, but additional to general surgery; to be studied when the latter has been mastered, and not before: consisting of prelections on gunshot and other wounds, diseases of foreign climates, peculiarities of camps and campaigning, hospital management, transportation of the wounded, billeting, and recruiting. We would have these matters, peculiar to actual service, illustrated by access to museums, hospitals, parades, drills; and, when practicable, by the improvement of such scenes as Chobham lately presented.

Once more heartily commending this attractive and valuable book to the careful attention of our readers, more especially of such as mean to "serve", we take leave of Mr. Guthrie.

THE INVALID'S OWN BOOK: a Collection of Recipes from various Books and various Countries. By the Hon. LADY CUST. 8vo. pp. 144. London: 1853.

How often does a stupid cook defeat the doctor! Times without number we have seen a badly cooked "plain mutton chop", or bad bread, retard convalescence: but we think that the most delicate stomach requiring animal food or bread, might with impunity receive these articles of diet,

prepared according to the precepts of LADY CUST. If it is not beneath the dignity of the physician to attend to the regimen of his patient, it is not beneath him to bear in mind such simple and excellent directions as are conveyed in the following and similar passages, in the little volume now before us.

"PLAIN MUTTON CHOP.

"Cut a chop from the lean side of a loin of mutton [or from the neck]; pare off the fat, and trim it neatly; beat it well to make it tender; and then, with a clear fire, put it on the grid-iron. Season it with pepper and salt; and, after turning it several times whilst it is broiling, press it, and if it feels tender, it is sufficiently cooked. Let the plate on which you serve it be very hot." (p. 113.)

"ENGLISH BREAD.

"After sifting a peck of flour into a trough, make a hole in the centre. Strain a pint of yeast through a hair sieve, mixed with a pint of water just warm. Stir into the yeast and water a small quantity of the flour, leaving it in the hole in the centre of the rest, to prove if it will rise. Set it in a warm place for an hour, when you will see the effect. Afterwards, mix the whole with two quarts of lukewarm water, and a pinch of salt; and, after you have kneaded it to a proper thickness, try it again in an hour after. Then knead it again, and bake it in a brisk oven. A brick oven is the best." (p. 110.)

"FRENCH BREAD.

"Commence as for English bread; but use milk instead of water with the yeast. When you have proved that it will rise, add two quarts of milk just warm, half a pound of butter, a little salt, and an ounce of sifted loaf sugar. Knead all together well; in an hour prove it again, to be sure of its rising. Make the dough into rolls about the size of a brick; lay them in a warm place for about half an hour, and then bake them in a brisk oven." (p. 120.)

Lady Cust describes the varieties of gruel, porridge, panada, and caudle, suitable for the sick; and jellies, puddings, broths, syrups, and cordials, are also fully explained. The methods of cooking fish and meats for invalids are very well set forth.

It is only in the chapter on "Teas" that the authoress ventures any hint as to the special cases in which her culinary preparations are to be used: but, as the following extracts will show, she does slightly invade the physician's province, when she speaks of elder flowers, cherry-stalks, horseradish, dandelion, and parsley, as remedies for dropsy.

"ELDER FLOWER TEA.

"Infuse dried elder flowers, the same way as common tea is made. Add a little acid, to hide the sickly taste of the elder. Sweeten to the taste!

"This is an excellent remedy to promote profuse perspiration."

"CHERRY STALK TEA.

"Infuse cherry stalks as above. Strain off the liquor.

"This is a French remedy for dropsy."

"HORSE RADISH TEA.

"Scrape horse radish root into a jug; pour boiling water upon it; strain it, and flavour it to the taste.

"This is another remedy for dropsy."

"DANDELION AND PARSLEY TEA.

"Wash and scrape six roots of dandelion, and six of parsley; add a pint of boiling water; set it by the fire to infuse for three hours. Add a pinch of salt to render it more palatable, or what is more efficacious, a little nitre.

"This is an excellent remedy in dropsy, acting powerfully on the kidneys." (pp. 3, 4.)

In the preface, we read:

"Many of the recipes were collected for the use of a beloved suffering member of my own family, since deceased, the companion of our residences in the Spanish Main, many of the Dutch, French, Spanish, and English West Indian Islands, and North America, by whose bedside the midnight hours were beguiled in compiling them."

From the circumstances which originated this publication, we expected to find in it many useful hints, and we have not been disappointed. It was compiled when attending upon a relative during a protracted illness in many lands.

CHEAP, NICE, AND NOURISHING COOKERY: or how Working People may live well upon a small Income. By the Author of "Cookery made Easy". 12mo., pp. 60. London: 1853.

THIS sixpenny book supplies a vacuum in the literature of culinary science.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

PROGNOSIS AND TREATMENT OF EPILEPSY.

The *Union Médicale* for May 17th and 19th contains an article by Dr. HERPIN, of Geneva, on the above subject, of which we now give an abstract.

In the *Union Médicale* for December 1st, 2nd, and 7th, 1852, M. Moreau, of Tours, relates nine cases of epilepsy, in which oxide of zinc had failed to arrest the disease, a remedy stated by Dr. Herpin to be of considerable efficacy. Seven of the cases were of the class stated by Dr. Herpin to be most amenable to treatment, and the medicine was administered according to the rules laid down by him in his essay, *Du Prognostic et du Traitement curatif de l'Epilepsie*, published last year at Paris. Dr. Herpin points out the causes of M. Moreau's want of success, in the following manner.

1. The first remarkable point which may account in a great measure for the different results obtained by M. Moreau and Dr. Herpin was, that eight of M. Moreau's cases were hospital patients, while Dr. Herpin's were private patients. Dr. Herpin observes, that physicians who have the charge of epileptic wards in hospitals, regard the disease as almost always incurable; while those who see the patients at home, as far as can be judged from their writings, form a very different prognosis. Tissot, Odier, De la Rive, and C. Vieusseux, all believe in the curability of a fair proportion of epileptic cases. A principal cause of the difference between the opinions of the two classes of practitioners is, that those in private practice generally see the disease from its commencement, while hospital physicians almost always have to treat severe or obstinate cases.

2. M. Moreau had only male patients; Dr. Herpin had more females than males. From an analysis of his cases, Dr. Herpin arrives at the following results:

Of twenty-six female epileptic patients, sixteen were cured, six were improved, and four were incurable.

Of twenty-four male epileptic patients, twelve were cured, four were improved, and eight were incurable.

There were thus twice as many incurable cases among males as among females.

3. With regard to age, Dr. Herpin has obtained the following results:

Of thirty-five patients under 20 years, eighteen were cured, nine improved, and eight were incurable.

Of nine patients aged from 20 to 50, five were cured, one was improved, and three were incurable.

Of six patients aged from 50 to 80, five were cured, and one was incurable.

The period of life from 30 to 50, furnishes a third of incurable cases; while the other two do not together supply a fourth. All M. Moreau's cases were from 19 to 50 years of age—the most unfavourable period.

4. With regard to the previous duration of the disease, Dr. Herpin finds that—

Of twenty-three cases, which had existed less than a year, fifteen were cured, five were improved, and three were incurable.

Of twenty-seven cases of from one to twenty years' duration, thirteen were cured, five were improved, and nine were incurable.

While nearly one half of Dr. Herpin's cases were of less than a year's duration, three of M. Moreau's patients had been ill from fourteen to twenty months, one for two years at least, three for six years, and one for about twenty years; the ninth had recent attacks of vertigo, but had probably had an epileptic attack six months before.

5. With regard to the number of attacks previous to treatment—

Thirty epileptic patients, who had had less than twelve attacks, furnished only three incurable cases.

Twenty-two patients who had had at least from thirty to a hundred attacks, furnished twelve completely obstinate cases, being at least five times as many as in the preceding category.

Of M. Moreau's nine cases, one, who was seized with vertigo, had perhaps had a fit; one patient had had only four attacks; one had had about fifty; four from seventy to eighty; one more than a hundred; and one more than five hundred. Besides this, one of the patients had, before the commencement of treatment, paralysis, denoting organic lesion of the brain, which was proved by the autopsy; and another had been twice insane. This latter circumstance was met with in one of Dr. Herpin's cases, in whom, though the conditions for treatment were otherwise favourable, the disease remained incurable.

Besides these causes of failure in M. Moreau's cases, Dr. Herpin points out that the want of sufficient judgment in the choice of treatment is perhaps a more powerful obstacle. He observes that, as long as we are unacquainted with the indications of each remedy for epilepsy, we must begin by giving that which experience has shewn to have succeeded in the greatest number of cases; then, in case of failure, we must have recourse in succession to other remedies of efficacy. By employing only one, especially in a number of patients placed in the same conditions as to age, sex, etc., we render ourselves liable to fall on the medicine which is not indicated. This is precisely what, it seems, has accidentally happened to M. Moreau.

Oxide of zinc is believed by Dr. Herpin to fail generally in epileptic patients in the vigour of their age, especially in men. Taking the whole of the cases placed in favourable conditions as regarded the number of previous attacks, and which were treated by oxide of zinc, he finds that there were twenty-six cures and five failures—all the latter being in patients between the ages of seventeen and fifty-nine years. On examining into the results of the treatment by oxide of zinc in men of between 20 and 50 years, in order that the conditions of sex and age might be the same as in M. Moreau's patients, Dr. Herpin finds six patients who were almost all in the most favourable conditions for treatment. In one, venesection appeared to have more influence than the zinc in producing improvement. Of the remaining five cases, there were—one cure without relapse, in a patient who had had only three attacks; two cures followed by relapse—in one of these the oxide of zinc failed on the subsequent trial; one in whom improvement was produced at the age of 15, but in whom the same remedy failed ten years later; and lastly, one in whom the disease altogether resisted treatment, although it had been commenced five days after the first attack. Thus, while the total number of favourable cases treated by zinc are in the proportion of five to six, adults furnish only three cases out of five, and in only one of these was the cure permanent.

In adult age, it is necessary to give zinc in large doses and for a considerable time; in childhood and old age, the same result is obtained from smaller doses, and, in some cases, from almost insignificant quantities.

The preceding observations appear to Dr. Herpin to afford sufficient reason for arriving at the following conclusions:

1. Oxide of zinc seems to be indicated as an anti-epileptic in children and old persons.

2. It often fails in persons of middle age, especially in men.

3. If it be employed in females, it must be given in large doses, and for a long time.

Whatever, Dr. Herpin observes, may be the remedies employed, it is of the highest importance that the disease be treated at as early a period as possible. He is convinced that, by perseveringly treating epilepsy from its earliest manifestation, there is a certainty of cure in a large majority of cases. At present, some mistake the first symptoms of the disease; others treat it for a time by means almost always inefficacious, such as bleeding, anthelmintics, etc.; others again try useless remedies, but timidly and without effect. A small number, chiefly hospital physicians, form a tolerably accurate method of the choice of a medicine and of the results obtained; but they are placed in the worst conditions for acting at the most favourable moment.

Dr. Herpin promises at a future period to publish in the *Union Médicale* the details of some cases in the practice of himself and others, giving both the successful and unsuccessful cases in the proportion of one to five.

BROMO-IODIDES IN THE TREATMENT OF INSANITY.

Dr. LUNIER, chief physician of the lunatic hospital at Niorte, is convinced that the bromo-iodides are useful in the treatment of mental alienation, and that they may often be substituted advantageously for cod liver oil. From many formulæ recommended by Dr. Lunier, we select the following:

R Potassii iodidi gr. xxxvj.
Potassii bromidi gr. xxv.
Pulveris radices gentianæ ðij.

Artemisiæ syrupi q. s. ut fiat massa, in pilulas lx. dividenda.
S. A pill thrice daily.

R Ferri iodidi gr. xxxvj.
Ferri bromidi gr. xxv.
Pulveris radices gentianæ ðij.

Syrupi corticis aurantii q. s. ut fiat massa, in pilulas lx. dividenda.

R Potassii iodidi gr. xij.
Potassii bromidi gr. viij.
Extracti gentianæ ðj.
Aquæ destillatæ ʒviij. Fiat solutio.

S. A tablespoonful thrice daily.

This solution can be given in the food, if care is taken to avoid aliments containing starch. *Annales Médico-Psychologiques.*

TOXICOLOGY.

CASE OF POISONING BY ACONITE AND BELLADONNA.

In the *Glasgow Medical Journal* for July 1853, Dr. J. A. EASTON relates a case in which death took place from the administration of aconite combined with belladonna. It formed the subject of a judicial investigation in Glasgow.

CASE. On Saturday, the 8th January, about half-past six o'clock in the evening, a young man, previously in good health, but suffering from slight headache, called at a drug establishment in Glasgow, to get advice from a medical student with whom he had been on friendly terms. The student administered a draught, containing twenty-five minims of tincture of aconite, twenty minims of tincture of belladonna, and a drachm of the tincture of musk. The tincture of aconite was prepared with sixteen ounces of the root of aconitum Napellus to thirty fluid ounces of spirit. Shortly after swallowing this mixture, the patient walked to a friend's house, about three-quarters of a mile distant. When the patient arrived at twenty minutes past seven, immediately on his entrance, he complained of "feeling queer", of being sick, and of experiencing a tingling sensation in his hands and arms. After remaining for a short period in the house, during which the hands and arms became so benumbed and powerless that, when raised, he could not keep them up, he walked again for about a quarter of a mile, and then was conveyed by an omnibus back to the place where he had swallowed the draught. He reached this about a quarter to eight; while there, he vomited freely, his speech was thick, and he staggered like a person intoxicated, though there was neither stupor, nor the slightest loss of consciousness. From the drug warehouse, the patient, accompanied by the medical student referred to, and by another friend, was despatched in a cab to the residence of Dr. Lawrie, which they reached at half-past eight.

Dr. Lawrie, in the discussion which followed the reading of Dr. Easton's paper at the Glasgow Medico-Chirurgical Society, gave the following account of the state in which he saw the patient.

"Mr. B., the subject of this case, walked into my room, supported on either side. His gait and appearance were those of an intoxicated man; but when he spoke, which he did with some effort, his articulation was so distinct, and his conversation so intelligent, that any idea of alcoholic intoxication was dispelled. He complained of a general feeling of discomfort and illness, of tingling and numbness in the muscles of the face, and of dragging downwards, especially towards the left side. His face was not flushed, neither was his skin cold, although the night was cold and stormy; and his pulse was about ninety, of fair strength. While I was examining him, he was seized with an inclination to vomit, whereupon I walked across the room to bring him a basin. On turning round with the basin in my hand, I found him by my side. The basin was replaced, and he vomited, standing with his hands resting on the basin stand. By restraining the effort to vomit, and by putting his right hand

over his lips, not a drop escaped from his mouth upon the floor. Observing that the matter which he discharged into the basin had the appearance of tea and bread recently swallowed, I gave him a tumbler of warm water, containing eight or ten grains of ipecacuan powder. He vomited again, still standing at the basin stand, supported by Mr. W., and did not complain of weakness or faintness. Believing that he was able to be moved, and being anxious that he should be in bed as soon as possible, I advised that he should be immediately taken home; that if his stomach were not emptied by the medicine which I had given him, a little ipecacuan wine should be exhibited, and that he should be freely stimulated. The party then left my house, Mr. B. walking with support, as he had entered it."

They proceeded in a cab to the home of the patient, which they reached at nine o'clock. On his arrival, he presented the appearance of a person dead drunk, and vomited twice. Shortly afterwards, convulsive movements took place in various parts of the body; the face became more deadly pale, and was covered with clammy perspiration; the pulse could not be felt; and at length, retaining his consciousness to the last, he expired at twenty minutes past nine, within three hours from the period at which he had swallowed the fatal draught.

Drs. Macgregor and Easton made an examination of the body two days after the death, and subjected the contents of the stomach to chemical analysis and microscopical examination.

The veins of the brain were unusually congested, and serous effusion existed in great quantity in the arachnoid. The lungs were gorged with very dark blood, and the right cavities of the heart were distended with similar fluid. The lining membrane of the stomach was of a dark red colour. With the exception of a slight thickening of one of the valves of the heart, the remaining viscera were in a natural condition.

The stomach, having been secured at both ends by two ligatures, was removed to the laboratory of Dr. Macgregor, where the contents of the organ were subjected to chemical and microscopical examination. They availed themselves of the microscope as a means of detecting the poison, though they also applied nitric acid and other chemical tests. A quantity of pure aconitina was examined under the microscope; but nothing more was observed than small masses of matter, dark in colour, and irregularly rounded in form. By way of comparison, a drop of the contents of the stomach, filtered, concentrated, and chemically prepared, was placed under the instrument; and an appearance was presented exactly similar to that yielded by the genuine aconitina. Drs. Easton and Macgregor, however, felt that it would be unjust to draw any conclusions from such an imperfect mode of judging; and, therefore, declared that, while the chemical analysis failed to detect aconite in the contents of the stomach, the microscopical examination afforded *no proof* of its existence. On the other hand, the unnatural condition of the heart, lungs, and brain, was precisely such as would be produced by this poison. They declared, however, that what the agency in this case was which overpowered the nervous system, and impeded the processes of respiration and circulation, the medical examination, and the chemical and microscopical researches by themselves, were insufficient to determine.

The medical student was indicted for culpable homicide. To this offence he pleaded guilty, at the spring circuit held at Glasgow in the beginning of last May; in consideration, however, that he had been on friendly footing with the deceased, and that he had acted from no other motive than to confer a supposed favour, he was sentenced only to imprisonment for fourteen days.

REMARKS. Dr. Easton thinks that death was owing entirely to the aconite. With the exception of unsteadiness in walking, the symptoms manifested were exclusively those of poisoning by aconite; while, with the exception stated, not one of the effects characteristic of belladonna was displayed. Belladonna produces flushing of the face, dilatation of the pupil, double vision, the seeing of imaginary objects, difficulty of swallowing, loss of voice, a scarlet eruption on the skin, and extravagant delirium. In the present case, the power of swallowing was perfect, the face was unusually pale, there was no mental aberration, and consciousness was retained till the last moment. Vomiting was present from an early period, as in cases where a poisonous dose of aconite has been taken; while in the majority of cases of poisoning by belladonna, though nausea is not infrequent, vomiting very rarely ensues. Hence he thinks that aconite is a much more energetic poison than belladonna; that it keeps the latter in abeyance, masking or repressing its effects, and thus giving support to the popular belief that two poisons cannot act at the same time.

It has been established by this case, that twenty-five minims of a tincture of aconite, of an ascertained strength, may take away life within three hours. This, Dr. Easton believes, is the smallest quantity yet known, or at least recorded, as having produced a fatal result. A much smaller dose, however, has been found to exercise a poisonous influence, from which the patient narrowly escaped. In the second volume of the *Lancet* for 1851, Dr. Topham of Wolverhampton narrates a case in which fifteen minims, taken in mistake by a female, produced inability to walk, convulsions in the face, etc.; but recovery ultimately took place, under the use of stimulants, in about twenty-four hours. The quantity taken in this case was probably equal to a little less than ten minims of the tincture given on the occasion referred to in the foregoing narrative. This preparation, to avoid circumlocution, Dr. Easton terms Pereira's tincture, from its similarity to that prepared according to the formula of the late Dr. Pereira.

On the other hand, ten minims of a stronger tincture—that prepared according to the formula of Dr. Fleming—have been given as often as three times daily.* In some instances, when even one such dose had been exhibited, very alarming effects were occasionally witnessed, such as the pulse falling in two hours from 70 to 44, becoming "weak and irregular", the patient at the same time being seized with vomiting, and, at the third hour from administration, experiencing "numbness and tingling", accompanied with "great powerlessness of the extremities, and a sense of weight pressing on the belly".† Further, according to M. Teissier (*Revue Medicale* for 1849), from one to two drachms have been given in the course of a day, with great benefit, in the treatment of rheumatism and other ailments! Dr. Easton calculates that the two drachms given by M. Teissier in the course of a day are equivalent to forty-eight minims of Pereira's tincture! He remarks that there must have been great carelessness in preparing tincture, or that some other botanical species of aconitum had been employed than the *A. Napellus*.

Still more enormous doses are reported to have occasionally been taken without a fatal result. In the *Lancet* for 1837, Mr. Sherwen tells us of a woman who swallowed by mistake "a mouthful" of tincture of aconite, but who recovered. Professor Taylor, in his work on Poisons, relates a case where recovery took place, though a quantity equal in strength to one drachm and four minims of Pereira's tincture had been swallowed at one dose; and in the same work we find a quotation from *Canstatt's Jahresbericht* for 1844, to the effect, that a patient ultimately recovered in three days, after having taken no less than ten drachms of the tincture of aconite! The escape from death in these and similar instances has been attributed to variation in the strength of the tincture employed. There are in this country no fewer than five different tinctures of aconite in daily and common use,—one adopted by the London College, another by the Dublin; the third prepared according to the formula of Pereira; the fourth from the recipe of Dr. Turnbull; and the last from that of Dr. Fleming. Dr. Easton does not believe that mere weakness of tincture accounts for the absence of a fatal result in those cases where large doses have been swallowed. He suspects that vomiting succeeded almost immediately after the introduction of the poison into the stomach, and that owing in great part to this, and not to mere weakness of the preparation, a fatal issue was prevented. Moreover, all the species of the genus aconitum are not equally poisonous. On this point Dr. Christison remarks:—"It has been rendered highly probable by the researches of Dr. Fleming, that the very peculiar acrimony of the monkhoods is a measure of their narcotic properties, and consequently of their medicinal virtues. I have found that *A. Napellus*, *Sinense*, *Tauricum*, *uncinatum*, and *ferox*, possess intense acrimony; that *A. Schleicheri* and *nasutum* possess it feebly; *A. neomontanum* very feebly; and that *A. paniculatum*, *lasiosomum Vulparia*, *variegatum*, *nitidum*, *Pyrenaicum*, and *ochroleucum*, do not possess it at all. These facts will direct the medical botanist in the choice of a species for medicinal use."

Two years ago, when Dr. Easton was engaged with Dr. Macgregor in the chemical examination of a case of poisoning by opium, it was suggested by the latter gentleman, that the microscope might be made available for confirming the presence of the crystals of morphia, which, by the usual process, had been separated from the meconic acid. The result was, that the perfect similarity as to shape of the crystals obtained from the stomach, with those of genuine morphia, left no doubt of the

identification of the one set of crystals with the other. In the case of amorphous bodies, however, such as aconitina, such a satisfactory corroboration of other proofs cannot be obtained.

POISONING BY ATROPIA APPLIED TO THE CONJUNCTIVA.

The *Gazette des Hôpitaux* gives an account of a case of poisoning by atropia, which is remarkable from the small quantity employed, and the place of application, viz.: the healthy conjunctiva. A patient in the hospital Saint-Antoine was labouring under double cataract, complicated with adhesions of the iris to the lens. In order to ascertain exactly the condition of the eyes, three or four drops of a solution, containing about one grain of atropine to two ounces of water acidulated with acetic acid, were instilled into each eye. Half an hour afterwards the patient suffered from vertigo and complained of disagreeable, unusual sensations; three quarters of an hour later he manifested all the symptoms of poisoning by belladonna, redness and animation of the face—pupils, though irregular, enormously dilated, incessant hallucinations, seizing the bed-clothes, and grasping at objects in the air. He could not raise himself from his bed, nor advance a step without being supported, as his limbs trembled and gave way at every effort. Pulse full, and beating one hundred and twenty. These symptoms gradually passed off, but the patient did not recover his normal condition for three or four days afterwards. Being interrogated upon the delirium and hallucinations of the preceding days, he had only a vague recollection of what had passed.

TOXICOLOGY IN THE SLAVE STATE OF VIRGINIA.

A dangerous horse is not shot—he is sold: and so it is with the slaves of Virginia: when convicted of poisoning they are "sold and sent to the south". The following we copy from the reports of the Medico-Chirurgical Society of Richmond, reported in the *Virginia Med. and Surg. Journal* for April 1853.

"Dr. BOLTON communicated a case of suspected poison by arsenic, in which the chemical analysis was conducted by Dr. Lewis and himself. Col. —, of Louisa, while eating ice-cream, perceived a peculiar taste, which aroused his suspicion and alarm. He took an emetic, and was attacked shortly afterwards by violent vomiting and purging. Under the care of Dr. Atkinson, of Henrico, he gradually recovered from the more alarming symptoms of poisoning, but was long debilitated, and his health was not completely restored until after a season at the mineral springs. Not having seen the physician in attendance, these general statements, derived from the patient's friends, were all that were in Dr. Bolton's possession.

"The glass of ice-cream, of which the patient had partaken, was examined, and after it had melted, a white powder was observed at the bottom. This powder was dried, and sent to Dr. Bolton for analysis. 1. A small portion of the powder was put in a reduction tube, carefully cleaned, and was covered with fragments of charcoal; upon being heated by a spirit lamp, a whitish ring was formed, then a broad ring with a distinct metallic lustre. 2. The same experiment was repeated with a different flux. 3. Some white particles were picked from the powder and placed upon a glass plate, and evaporated with an odour resembling phosphorus. 4. Similar particles were dissolved in boiling distilled water; solution of nitrate of silver had no effect; on adding ammonia, an abundant canary yellow precipitate took place. 5. The same solution was treated with the ammonio-sulphate of copper, and an abundant green precipitate was the result. This showed that the preceding reaction was not caused by phosphoric acid. 6. Marsh's process was now employed. Hydrogen was evolved from an apparatus containing rain-water, sulphuric acid, and granulated zinc. A piece of white porcelain was exposed to the gas without acquiring the slightest stain. A solution in boiling distilled water of the ring procured by the reduction process, was then added to the apparatus, and numerous distinct deposits were procured upon a slip of glass and upon a piece of white porcelain. 7. Reinsch's test was next tried. A solution of the powder was placed in a clean test-tube, and one-sixth part of muriatic acid was added; clean slips of bright copper foil were introduced. Upon boiling, a copious grey coating of the metallic surface took place. 8. A slip of copper, thus coated, was gently heated, and a sublimate was obtained. This was treated with ammonio-nitrate of silver, and ammonio-sulphate of copper, and the characteristic reactions of arsenic with these tests ensued. 10. A solution of the powder when treated with hydrosulphuric acid, threw down the rich golden sesquisulphuret of arsenic. 11. (*Quantitative analysis.*) One grain of the powder, which was apparently

* An Inquiry into the Physiological and Medicinal Properties of the Aconitum Napellus, by Alexander Fleming, M.D., p. 146.
† Op. cit., p. 148.

composed of a white mineral pulverulent substance, mixed with a coarse powder like bran or corn meal, was dissolved in boiling distilled water. This was precipitated by sulphuretted-hydrogen, and re-dissolved, to purify it, by ammonia, and again precipitated by hydrochloric acid. The precipitate was carefully weighed, and amounted to one grain—equivalent to four-fifths of a grain of arsenious acid. 13. (*Microscopical analysis.*) The ring procured by the reduction process exhibited, under the microscope, octohedra of arsenious acid.

"Notwithstanding the conclusive nature of this evidence, the examining court before whom the negro suspected of perpetrating the crime was arraigned, found no cause for trial, and he was accordingly sold and sent to the south."

OXYGEN AS AN ANTIDOTE TO THE DELETERIOUS EFFECTS OF ANÆSTHETIC AGENTS.

Dr. S. ABRAHAMS, of New York, writes thus to a friend in Canada:—

"An accident which happened last season in this city (New York), as similar occurrences have often previously done, has brought before the medical profession, a remedy or antidote to the deleterious effects of chloroform, as an anæsthetic, which promises, in point of usefulness, to be second only to that of the discovery of anæsthetic agents themselves.

"The case is as follows:—A young man, attached to the Laboratory of the New York Medical College, became asphyxiated from the inhalation of the vapour of chloroform, and so far had its effects been carried, that he became pulseless, and all hopes of his resuscitation abandoned; and as all the usually recommended remedies had been tried without any success, nothing but the death of the young man was looked for, when I proposed as a *dernier ressort*, the application of *pure oxygen gas*, as the only chance by which resuscitation could be brought about; but at the time the proposal met with opposition from the medical men present, who were anxiously watching what seemed to be the expiring efforts of the poor boy, expecting each moment to be his last. Having, however, consented, the gas had not been more than a few seconds applied to his nostrils, when he who was apparently beyond the help of human aid, and absolutely *in articulo mortis*, arose and placed himself on a chair, proving most conclusively, how correct I was in proposing the application of oxygen gas as a remedy against the deleterious effects of chloroform as an anæsthetic.

"I am inclined to believe that the same agent might be used with advantage in cases of drowning, where the body has been recovered from the water while it is still warm; and I am sanguine of its success where persons are suffering from the inhalation of the fumes of charcoal, or from the fixed air (carbonic acid) of pits, mines, etc. I might mention that oxygen gas is almost instantaneously generated from the chlorate of potash, or what is always more readily obtained, nitrate of potash. Either of which placed in a metallic spoon or shovel, and held over a gentle heat, will evolve the gas most profusely."—*Canada Med. Journal*, January 1853.

EDITOR'S LETTER BOX.

THE CLUB SYSTEM.

SECOND LETTER FROM S. T. TO THE EDITOR.

SIR,—Thank you for so quickly and energetically seconding, in your last two leaders, my letter upon that threatening down-draught of our profession, the *abuse of the club system*. I am glad you think with me, "that our Association does possess the power" of rectifying the evil. Only let the subject be earnestly taken up by the members, especially in the Branch meetings, and we may look forward with reasonable hope to a reform which will benefit not only the profession at large, but also those who properly ought to constitute the class of recipients of club medical relief. Perchance, in doing this, the Association may discover that its recent growth has given it greater moral influence, both with the profession and the public, than it is yet quite aware of.

It seems, moreover, that it is not in England alone that club abuses prevail; the extract from the French *Union Médicale*, published in the *Journal* for Sep. 2nd, shows that, across the Channel, not only are certain well-to-do persons willing to impose upon medical men by availing themselves of provisions made for, and *calculated pecuniarily* for, the poor; but that

medical men there, as well as here, are found to submit to the imposition, in some cases perhaps from indifference, in others from fear, and probably, as here, in not a few, from the hope that the acceptance of the club pittance from one member of the family will be the stepping-stone to substantial fees from the remainder—a motive especially unworthy, when made the means, as it often is, of insinuation into a family attended by a brother practitioner. In Scotland, too, judging from the letter of the northern correspondent of the *Medical Times and Gazette*, published Sep. 10th, the club abuse is rousing attention: that attention, however, ought to be directed to its reform, and not to its wholesale condemnation, as expressed by the writer.

Agreeing generally with the most important remarks upon the club system made in your leading articles, on one minor point at least I differ. You say, "the secret cause of *all* the mischiefs that accrue to the profession through club appointments" arise from the desire, on the part of leading members or conductors, to show a flourishing balance sheet." Now, I acknowledge that much mischief does accrue from this cause, but not all; part is due to the members of our profession themselves. In many clubs, the scale of the doctor's remuneration is fixed by the whole body of the members; and, if the bulk of these are labouring men or artisans, accustomed to comparatively small expenses, and to deal in small sums, they naturally think that the aggregate amount, made up of half-crowns, or other such sum, is something specially profitable. They have no rule or idea by which to measure professional remuneration; and when they find the doctors making an object of, or canvassing for, the privilege of attending the club upon their own terms, what other idea can they entertain? What other rule have they to go by? Now, I am very far from condemning the attendance upon labouring men's clubs at the very common rate of four shillings per member annually, or even in some instances for less; for I believe that the sum, small as it is, constitutes as much as can be afforded by the average of the class: what I contend for is, that the recipients of medical attendance on such terms ought to be clearly shown that they are not remunerative; that, if their doctor does his duty as he ought to do, he does it from a sense of duty; but it should also be made clear that such a sense of duty cannot be in action with him if he is required to attend, upon similar unremunerative terms, individuals whose means, he is aware, enable them to pay a reasonable medical bill.

I lately had the opportunity of giving to the poorer members of a club a practical exemplification of the above. I was offered the medical attendance of a certain number of females, at an advance on what they had previously paid. The majority of them I would gladly have attended, for I knew the sum they offered was as much as they could well afford. On looking down the list, however, I found the names of two or three persons, who not only in times past had paid me proper accounts, but who could do so again, if requisite; and I accordingly declined the offer made. True, self-interest was here a considerable actuating motive; for it would have been very foolish to undertake the attendance of thirty people, for the sum I should probably, or possibly, draw from one. The lesson, however, was not the less useful; and, at the same time, I ought to say that, had it not been for the two or three interlopers, I would gladly have given my services to the others.

To return: *all* the mischiefs, then, of the club system do not originate with the leaders or directors of such associations, but actually arise from the ignorance of the great bulk of the members as to the nature of professional remuneration; ignorance, moreover, fostered by the conduct, or taken advantage of, by some members of our profession. This ignorance, however, cannot be pleaded by the gentlemen, clergy, or high class tradesmen, directors of Friendly Societies, Dispensaries, etc.: they must know, when they admit members indiscriminately, as they do, at the low rate of medical remuneration adapted to the slender finances of the labourer, that they are wronging the medical officers of their charities. This, however, is but part of the system of gratuitous or semi-gratuitous service in hospital, dispensary, and consulting room, looked for almost as a right by an exacting public, and yielded by medical men. It will assuredly meet its reform ere long. But for reform of every kind, we must have what I fear is more easy to suggest than to bring about—union among ourselves; without it we are all but powerless. The men of Canterbury have shewn what may be done by united action; and there is no reason why well combined force—especially among the members of the Association—should not be brought to bear in every separate locality, sweeping away that distrust of one another, which ever stands in the way of decided steps, and of independent action. How few are there in

our profession, who do not know from experience how difficult, and at times how impossible it is to maintain that independent course which their feelings dictate, when those feelings are put in competition with the claims of a family dependent upon them for support, and for provision, which cannot afford the loss of a fraction even of a bare income.

And why does an independent course, followed by a medical man, as regards the public, involve risk to most sacred claims? Simply because each medical practitioner distrusts his neighbour, and feels that if he resigns his club or his union, because he is under-paid, or because undue advantages are taken, that probably there are two or three neighbours ready to step in.

It is almost trite again to remark, that it is vain to look for a remedy without united action among ourselves. It is strange how men can be so blind to their own interests, as not to see the immense power which union would place in the hands of every individual medical man. Moreover, the united action of a body of men, provided their motives are right, the reforms they propose just, and the claims they advance reasonable, brings with it a moral power, out of all proportion greater than that exerted by the agency of an individual, however self-sacrificing. According to my own experience, at least, it is much easier to resist some great encroachment, to "do some great thing", than to keep up the warfare against the continued petty grievances that spring up under such a system as the present club arrangements.

It is impossible, without serious injury to those interests which a man must preserve, and without loss of true dignity, to be constantly cavilling at little matters, resisting the introduction of doubtful members. These things can only be met by the laws or rules of a collective body, such as the medical men of each district might and ought to form.

I fear, Mr. Editor, I have already encroached far too much upon your valuable space, but having said so much about union in our profession, I cannot close without briefly laying before the members of the Association a plan of union, which might embrace a large proportion—it is vain to hope all—of the medical men in the kingdom.

It perhaps is true, that even the annual guinea fee required by our present terms of membership, is an object to many medical men of small incomes. Would it not be possible to institute an honorary or branch membership, which, involving only the payment of such a small fee as five shillings, would not confer the privilege of the receipt of the Journal, but confer the other privileges of membership, not connected with the disposal of funds derived from the higher fee? For the benefit of all the members, honorary and otherwise, I would propose the publication of a small monthly, or quarterly periodical, devoted solely to our political and ethical concerns, making such publication the medium of connexion between the entire body of medical men composing the Association. Such a publication would free your own columns from much correspondence of a non-scientific character, and afford you more space for practical matters, while at the same time it would offer a ready and recognised medium for communications relating to the ethics and political constitution of the medical body.

As I have found it necessary in the course of my remarks to bring forward personal experiences, perhaps you will permit me to avoid the charge of egotism by retaining my signature of

S. T.

September 12th, 1853.

THE CLUB SYSTEM.

LETTER FROM CONWAY T. EDWARDS, ESQ., TO THE EDITOR.

SIR,—S. T. has struck a blow in the right direction; and I wish to second him. So open have our hearts been to our suffering fellow-creatures; so freely have we given of our gifts of healing; so willingly, and with such tenderness have we ministered at the bed of sickness; so contented to take thanks for our pains, and bear pains mental and bodily for our exertions; so quietly do we pass over neglect and ingratitude, so abhorrent to the feelings of the great majority of our brethren is a determination to obtain by legal means our legal dues; that society generally, and public bodies particularly, believe that the medical profession, as a body, should work for the lowest amount of money possible, if, indeed, for money at all. The truth of the first position being proved by the remuneration given by clubs of all kinds; and of the last, by the unremunerated services of hospital surgeons.

But, whilst the conduct of the public is unjust and ungenerous towards us, we must feel that we *alone* have been to blame;

and that it no more would have dared to lay its icy fingers upon us, than on the legal and clerical professions, if we had not freely held forth our hands to meet them. But on all sides labour is beheld asserting her rights. Everywhere the overworked and underpaid labourer has obtained a recognition of his services; through hunger and thirst, the dauntless and living determination of his British heart has beaten down opposing forces, and won the object for which he fought. Are we more helpless than the labourer? Or are our sufferings but delusions of the mind? In courts of law we suffer; by public bodies, and the poor-law especially, we suffer! In pocket, in honour, in our gentler feelings, and in everything which ennobles and sanctifies humanity, we suffer! We suffer; for we are *dis-united*, and therefore helpless.

We fear a phantom! In its incarnated state, all kinds of quackery it patronises!—all the quack pathies it patronises!—all the pills, mixtures, liniments, and ointments, that ever were invented, it patronises! No matter how *indecent* the statements; no matter how absurd the assertions; no matter how lying the advertisements which treat of relief from suffering, it believes all—it patronises all! And is this the thing to which we should sacrifice our integrity—our freedom? Is there no great principle for which it should undyingly contend? There is!—it demands a sacrifice: are we prepared to make it? Ah! how timidly we go to work! Clear, defined, unmistakable, before us lies our grievance—by its side, our remedy.

One complains, another complains. A. is afraid of B.; B. is fearful of C.: and A. B. C., not being equal to each other, shrink into themselves at the bare thought of attacking the *fons et origo mali*. We want a master mind to marshal A. B. C., and to march them to the fight.

Yet, how bravely A. B. C. contend for that miserable bone thrown amongst them by the most Christian Poor-law Guardians! How fiercely they fight, *i.e.* canvass, for the honour of attending the "Gemini Club", at five shillings for any number of babies! or the "Pot and Pipe Friendly Society", at "2s. 6d. per head, per annum"! How they bow down in the dust, and defile their fathers' graves, but inwardly anathematise their own sad fate, when they arise, victorious from the fray, the Corypheus of that Pot and Pipe Society!

Oh, unhappy, yet noble, profession, how long art thou to be torn in pieces by thy children? Where are our Colleges? Are they sleeping, dreaming, or paralysed? Have they heart, soul, or sense? Or, as they float on the Pactolian stream which flows from us, do they laugh us to scorn, and sing to each other "Io Pagan", as we sink beneath a most unequal fight.

They are, one and all, dipped in Lethe! Shake them—they yawn, and heave, and sleep again. No generous emotions throw any warm sunlight through their souls. They care not for us: our sufferings are nothing to them! What is it on which their heads repose? A pillow, which they have stamped with these words—"Our vested rights!"

We know the foul disease which is wearing us away. The remedy is sure, if we have courage to face it! Can we bear the knife,—not in a tedious, trying dissection,—but in a daring and effectual sweep, once and for ever, through the diseased parts? I think we can.

At once, then, resign all public appointments; and remembering *with what, and for what we fight, refuse to fill the gap our brother leaves*. And when remuneration shall receive the sanction of our now awakened Colleges, and is allowed by the whole body of the profession to be just and good, then with one heart and voice join in the reinstatement of our brother in the place which he vacated for the good of society, and welfare of our profession.

To effect this, a central committee should be formed in London, and local committees in every city and town of the United Kingdom; and when the sense of the profession is taken, and an universal assent is given to the great proposition, action begins, complaints cease, and tyranny shall no more have dominion over us.

I am, etc.,

CONWAY T. EDWARDS.

Bath Easton, September 8, 1853.

[The club system evidently falls within the province of the Medico-Ethical Committee appointed at Swansea; and, as the first meeting of that committee is probably to be held within a month or six weeks in London, good might result from Mr. Edwards and others specially interested in the subject, communicating at once with the secretary of the committee, W. H. Michael of Swansea. EDITOR.]

CHLOROFORM IN LABOUR.

LETTER FROM J. DEANE, ESQ., TO THE EDITOR.

SIR,—How is truth to be discovered in medicine, or in any practical art? Simply by observing facts, and by reasoning on them. Above all things, we must not be weary in the discussion, and end it by saying, "We have had enough of this". Apathy has in all ages as much retarded science as abstruse hypothetical reasonings.

Dr. Simpson's "Letter on Chloroform" has been cleverly handled in a recent number. If, at the same time, one-half the genius and acquirements which dictated that letter had been employed in the personal observation of anæsthesia in labour, pages 761 and 762 would have been otherwise filled. I do not think that any specimen of special pleading, however well managed, can stamp Dr. Simpson's reasonings as fallacious, or throw his discovery to the winds.

Mr. Bloxam begins with some correct remarks about the dangers of analogical reasoning. If Dr. Simpson had recommended chloroform from analogies, however strong, he would assuredly have been at best at the threshold only of his discovery. Such, however, is not the case. All through his letter, you see analogy exactly where it should be. He is reasoning against prejudices, and he defends his point by showing that the arguments advanced against him are not admitted to be valid except in their solitary application to chloroform; and that, under precisely similar circumstances, the same argument is not admitted against anything else. Now, if the analogy holds in the only point in which it is used, it is assuredly valid, and you cannot argue against it by proving it not to hold in some other respects in which no analogy was asserted or claimed; otherwise all analogical reasoning might be refuted by the *reductio ad absurdum*. Dr. Simpson thus meets objections by showing that they prove too much—a mode of reasoning which can be answered only by showing that the analogy does not hold in the point at issue. It is bad reasoning to argue against the analogy by saying that it does not accord in some feature not bearing on the illustration.

Thus the analogy is contested in paragraph 9, between the use of forks in eating, and the use of chloroform in labour. "A fork may aid in eating", but he does not see how chloroform can aid in labour. Dr. Simpson would reply: "I do not claim the analogy on the ground of aid (although I might reasonably claim it), but on the ground that 'all the tendencies of man in a civilised state of society are to intermeddle with, and change, and improve, as he conceives, the action of almost every function of the body; and each improvement has, at the time of its introduction, been duly denounced.' The analogy is on the disposition and 'the necessity of intermeddling, changing, and improving the functions of the human system.' It is an argument against the notion, that whatever is natural in the human system is right and desirable. It is natural to eat with your fingers; it is natural for disease to go on uncontrolled when the *vis medicatrix* cannot cure it; natural for pain of all sorts to go unrelieved, from the twinge in a rheumatic joint to 'the pain for which there is no other name but *agony*'; just as it is natural for thorns and thistles to show themselves under the most careful tillage. But 'it is the tendency of civilised man to intermeddle with and to improve' these matters. Here, surely, the analogy holds, and is as perfect as such a form of reasoning possibly can be.

Another fallacy in Mr. Bloxam's letter is what is called "ambiguous middle term". Thus, to meet the assertion that it is hardly worth while to relieve the pain of labour, Dr. Simpson argues that we constantly use measures to relieve colic, sciatica, pleurodynia, gout, and all the "dolours" that flesh is heir to; and then he inquires why we are to except the pains of labour, and refuse to administer relief when it is within our power? Mr. Bloxam then argues (paragraph 3) that, "on the same principle, if a man be suffering pangs of conscience consequent on the commission of crime, it would be our duty to relieve his suffering by putting him to sleep with opium". Dr. Simpson speaks, as a medical man, purely of physical suffering; Mr. B. speaks of human suffering in its widest sense, including the mental and the spiritual. The ambiguous middle term is the word "suffering" or "pain". We have here a compound error in reasoning: in addition to the ambiguous middle term, we have the application of an analogy in a bearing for which it was not designed, and that very bearing is the substitution of the word "suffering" in a universal sense instead of a particular. Dr. Simpson does not even argue that all pain should be assuaged by chloroform; he would not recommend it for the

pain of incipient meningitis, and for many other forms of suffering. In the paper now before us, he is arguing for it only in the last stage of labour. Will it be believed that, in meeting the quotation just given from Dr. Simpson, the respondent argues that "the desire to relieve existing discomfort is under many circumstances a temptation to sin? If the immediate relief of existing bodily discomfort were in all cases desirable, drunkenness, lasciviousness, perhaps all the sins of life, would stand justified." The bodily "discomfort" of one writer, and "the gout, and other innumerable dolours that flesh is heir to", are two absolutely different ranges of ideas, and are used all through Mr. Bloxam's letter under the ambiguous words "pain", "suffering", "bodily discomfort".

In the sixth, seventh, and eighth paragraphs, we have a specimen of the *ignorantia elenchi* fit for a college exercise. Dr. Simpson had argued that the pain and extreme fatigue caused by the last few miles of a journey of thirty miles on foot have a strong resemblance to the last stage of labour, being pain, weariness, exhaustion, and all in both cases the result of excessive muscular action; and he argued that, as in one, so in the other, something to carry the parties engaged in these modes of travail easily through this last stage is as judicious as it must be acceptable: in the former case, a conveyance, some good man's carriage; in the latter, some quiet anæsthetic, to relieve the pain and fatigue of labour. This may be a good argument, or it may not. How is it met? The words "ordinary fatigue of walking" are substituted for the words "a continuous journey of thirty miles on foot" (Simpson); and then it is argued that "the ordinary amount of fatigue that attends upon ordinary progression is conducive to health"; and half a page of good writing is devoted to prove the statement, and Dr. Simpson's proposition is forgotten. If you wish for a case of *ignorantia elenchi*, you cannot, Mr. Editor, find a better than this; and if you wish a description of this form of fallacy, you cannot find a better, not even in Whately's *Logic*, than the following, which I copy from the second paragraph of Mr. Bloxam's letter: "It consists in substituting some other proposition for the one primarily under consideration. The adopted proposition is perhaps made good, or it is at any rate presumed to be so. No attempt is made to show that the two propositions are similar, analogous, or parallel to one another; but, as there is an obvious or apparent resemblance in some point of view, they are presumed to be parallel cases for the purpose of the argument. This is a very hazardous mode of proceeding, though a very convenient one in some respects."

When Mr. Bloxam's letter was penned, I can almost imagine him to have said, "Having gone thus far, what other sophism have I not used? There is the *petitio principii*; I must not forget to give a specimen." Accordingly, paragraphs 11 and 12 constitute a very fine specimen of this fallacy. The reasoning is good, except that, unfortunately, it is all based on the assumption that anæsthesia adds to the danger of labour. This happens to be the question. Those who have used it, assert it; if properly administered, to be innocent; that the labour is quicker from the relaxation of the sphincters, and from the relief of cramp, and of all irregular actions about the uterus; and that the patient is better and stronger afterwards; and therefore, for the last advantageous considerations (other considerations being about equal), they recommend chloroform to abridge human suffering; and they fortify their position by the statement which Mr. B. admits in his last paragraph, that "patients, when submitted to the pain and shock of surgical operations without the use of anæsthesia, recover in smaller proportions than those who are operated on under its influence."

I do not think I have in any way misrepresented the strictures upon Dr. Simpson's letter. I think the charge of loose reasoning must rebound on Mr. Bloxam. To what strange resorts are men reduced, who reason against improvements, instead of fairly endeavouring to test them! I am, etc.,

J. DEANE.

Chatteris, Cambridgeshire, Sept. 13th, 1853.

THE NEW VACCINATION ACT.

LETTER FROM FRED. JAMES BROWN, M.D., TO THE EDITOR.

SIR,—Since the bill rendering compulsory vaccination the law of the land has passed, I beg leave to suggest the following for the information of those that may have the framing of the machinery by which the bill is to operate.

That printed certificates be issued by the registrars to all qualified medical practitioners, of a form adapted for the entry of particulars respecting the progress of the vaccine-pock, the

date of the appearance of the areola, the continuance of the same; the date of the falling off of the scab, etc.

Certificates expressing particulars would thus become documents of value, enabling physicians, in future years, to judge for themselves of the nature of the pock that their patients had had in infancy. We frequently see persons suffering under variola that have been previously vaccinated; but we have, at present, no means of knowing whether these persons have had the true cow-pock.

Another suggestion is that every registrar should be required to ascertain, by reference to the directory, that the practitioner signing the certificate is really a qualified medical man.

If certificates be loosely received (as they now are for deaths, in many instances), no dependence can be placed upon their accuracy.

I am, etc.,

FRED. JAMES BROWN, M.D.

Chatham, September 8rd, 1853.

[Dr. Brown ought to press his important suggestions in the proper quarter. From the tenor of our correspondence, however, we fear that the Vaccination Act is doomed to prove a failure. ED.]

THE COLLEGIATE SYSTEM.

LETTER FROM W. COLLYNS, ESQ., TO THE EDITOR.

SIR,—Grateful as every one of our profession must be to Sir Charles Hastings, the founder of our Association, and gratified as every medical man must be at the eminent success of Mr. Propert's noble and philanthropic institution, there still remains a desideratum of the first consequence to society—the general establishment of collegiate residences for medical students obliged to leave the parental roof.

It was a great omission in the proposed bill for medical reform, that there was no clause requiring a certain course of preliminary practical study, as a pupil, with some legally qualified general practitioner, before the intending student should be admitted to matriculate at a medical college. But when the state of pupillage is past, and the young student enters one of our great medical schools, in the metropolis or elsewhere, he has no retreat, within which he may retire for study, under the certain surveillance of a superior, who could assist his studies, and protect him from the numerous temptations, so attractive, and so fatal to the welfare of unsophisticated youth.

It appears to me that there should be some sort of collegiate establishment attached to every large medical school, the superior of which should be resident, and an active intelligent person, who should attend to the discipline and order of the house, superintend the meals in the hall, enforce the closing of the house at a proper hour; and whose report of the students' conduct should always be required by the examiners at the boards, when the pupil applies for his license or degree.

Having educated thirteen pupils, during a practice, in the country, of forty-five years, and having seen the sad demoralising effects of the present system of irresponsible conduct (and more particularly in one instance in my own family, which entailed upon me great expense, and much misery), I may be excused having made this suggestion. If through your kind offices, attention can be drawn to this momentous subject, so as to obtain an efficient remedy, it will be a source of great and lasting satisfaction to

Yours, etc.,

W. COLLYNS.

Harlow, August 12th, 1853.

[Mr. Collins has touched upon a subject of surpassing importance. When parents send up their sons to study medicine in a metropolitan school, and place them, inexperienced and raw from the country, in a solitary lodging, they ought chiefly to blame themselves for the vicious courses of their children. A collegiate, or, better still, a domestic, home is far more likely than a famous school to tell favourably upon a youth's future career. EDITOR.]

NEWS AND TOPICS OF THE DAY.

TABLE TURNING.

[The following letter requires no commentary. We pity the parishioners of Patcham and the troops at Brighton. EDITOR.]

TO THE EDITOR OF THE BRIGHTON GAZETTE.

"SIR,—Though men cannot now believe in direct miracles, they must be startled by witnessing experiments and results

which superstition or imagination might easily attribute to the supernatural, and in reality without wonder.

"Within a few years, sensible evidence taught a few that Mesmerism (so called) was not simply ideal. The animate was found to act wondrously on the animate; and it may not have been blind conjecture that the will was an agent of mighty power over the nervous and muscular system.

"Whether, or to what extent, clairvoyance has a reality, and if so, what are the agencies which, acting and re-acting on each other, produce such startling effects, is a problem yet unsolved.

"Far more rapid in its progress, quite as startling in its results, and not less difficult to fathom, is the process of *table-turning*—no longer questionable, but a fact accomplished. For it has become the amusement of millions, young and old, the unlettered stare with astonishment, thousands cannot believe their senses, the scientific think and think, and are puzzled, and differ, and can come to no conclusion; and the great Faraday, the giant of his profession, can publish in the *Times* the most puerile farrago on this subject, to him so clear and intelligible!

"Table-turning, then, the world begins not to dispute; but table-talking, and table-telling, and table-dancing, and the fantastic freaks of tables of all colours, and all woods, and all shapes, people do not believe. They say they can't believe, and multitudes that they won't believe, and that nothing would make them believe.

"Then, sir, let me tell you, for the instruction and benefit of your readers, the following simple unvarnished facts, to the statement of which I attach my name and address, as a guarantee for their genuineness and correctness; and let me state, that any collusion, or combination, or deception, by one or more individuals present, was utterly impossible.

"On the 12th inst., I was visiting at Crohan House, the residence of R. Patton, Esq., county Donegal. From among a party of ladies and gentlemen, nine were solicited to take their seats round a large rosewood drawing-room table. After forming an uninterrupted link with our little fingers, we all agreed to will that the table should turn to the left. About half an hour elapsed without any apparent motion, when I said, 'let us alter our intention, and will it to the right'. We did so, without in any respect changing the position of our hands. Almost immediately the table began to creak and shake a little, and soon to turn slowly, and then more rapidly revolving and progressing. It was arrested by an inequality in the carpet, and for a quarter of an hour seemed quite motionless, when it again started off rapidly, and carried us all with it, *volentes volentes*, but was again stopped by the uneven carpet. The patience of some of the party began by this time to give way. One or two raised their hands, and finding the chain broken, we all did so. Four of the same party then formed a similar chain round a small table, about three feet in diameter, standing upon three legs, without castors, which in less than a minute started off, revolving with great velocity—so great, that the persons whose fingers formed the chain on the table were unable to retain their balance, and one after another were prostrated on the floor, to the no small amusement of the bystanders. However, the moment the table was again touched by more than one of those who had been engaged in operating on the large table, an immediate effect was produced; and, as in the case of the larger one (which we had often tried), when revolving rapidly to the left, on my saying, 'now we will it to the right', *citius dicto*, to the right it went, with equal velocity. 'Quicker, quicker,' we all cried, and quicker it went; and at the command 'stand still,' it equally and as quickly obeyed.

"One of the party then suggested that the table might be asked to tap on the floor. While revolving, it raised one leg, and tapped loudly and distinctly. Three taps were then required of it: three it gave. It was then ordered to stand still and tap: it obeyed. By this time, either the table or the individuals became so charged with the occult power, that by simply touching the table, without any manual conjunction, it immediately performed a rapid revolution. One lady in particular set it wildly off the instant her fingers touched it. My own power over it seemed next to hers; but certainly inferior.

"The table was then told to tap with one leg three times: it tapped at once three times, loudly and clearly. Then with each leg, in succession: it failed not. We then desired it to go round, and then suddenly to stop, on which I asked of it, how many children a certain lady present had? It raised its leg, and gave the accurate number of strokes, distinctly and correctly. How many Irish miles, we next inquired, is it from Ramelton to Rosnakeel? The answer, eleven, was unmistakably plain and correct. How many people were round the

table? Five. Correct. How many in the room? Right. The table could never be made to move after indicating the number till a fresh question was put. 'How many framed pictures were there round the room?' Nine. Right. 'What o'clock is it?' It was a quarter after nine. It gave nine distinct strokes (afterwards, when a quarter to ten, it struck ten). One of the party then proposed that the table should be carried upstairs to the room of an invalid lady who was extremely interested in the 'séance'. I opposed the movement, on the ground that the experiment must fail. I was outvoted, however, and it was carried by four persons, maintaining the chain perfect. The instant it touched the floor, off it went again, at my bidding; and its race was quick or slow, to the right or left, backward or forward, just as we willed it. I might say, as I willed it, or the lady before named, for we often did so separately, and alone. But, stranger still, my order was that it should dance, it danced a merry hornpipe; that it should shake, it rolled rapidly round, and shook as if in a fit of ague, amid one irresistible laughter. It obeyed the command to jump till it lost its balance and tumbled over. Our order that it should raise itself was unavailing. On request, it bowed most politely, and in like manner it played hide and go seek, when told to follow any one through the room; it was commanded to leave the room. No sooner said than done; to save it some broken legs, we dragged it back just as it was reaching the stairs. In telling the ages of persons between forty and fifty, it was mostly correct, always approximately, and the one year's variation from the truth in an instance or two, arose, I believe, from miscalculation on the part of some of us, or from want of sufficient observation. Subjects for experiment at last began to fail us, and finally, it was asked, when our amazed patient would recover: in three days was the immediate reply, and loudly proclaimed answer. Time sufficient has not yet elapsed for me to hear the result.

"These, sir, are a few of the numerous experiments we made so successfully. What a wondrous novel power! Muscularity it cannot be; odyle, or some corresponding power, it may be; electric, or galvanic, or something similar, perhaps, not now to be characterised by name. I leave the question to the public, without note or comment. Gladly should we hear again from Mr. Faraday on the subject. "I am, etc.,

"HENRY ALLEN,
"Vicar of Patcham, and Chaplain
to the Troops, Brighton."

August 23rd, 1853.

CHOLERA AT NEWCASTLE. Up to Monday, 133 cases of the Asiatic Cholera have occurred at Newcastle, of which 53 were fatal. The disease has also broken out at Hexham and at Morpeth. Mr. Grainger has been in Newcastle since Friday, co-operating with the authorities to improve the sanitary state of the town. We cannot expect that we can long enjoy an immunity in this metropolis; and yet our sanitary condition is as imperfect as it was in 1849.

THE CHOLERA. The epidemic is on the decline at Copenhagen, and the people are a little recovering from their alarm. Apprehension had, however, risen so high, that more than 40,000 people had fled from the capital. It is computed that the population was reduced to 90,000, and that about 4,000 persons had fallen victims to the disease. The cholera has again broken out at Moscow, and one of the first victims has been Dr. Siervruk, Professor of Anatomy to the University, who died after two days' illness. The disease is said to have appeared at Dantzic. We regret to learn that cholera, which at first only presented "sporadic" cases in Hamburgh, has now assumed an epidemic form. Of 180 cases, two-thirds proved fatal, thus exhibiting the malignity of the disease.

MUSEUM OF PRACTICAL GEOLOGY IN GLASGOW. On Wednesday, August 31st, a meeting was held in Glasgow, presided over by the Lord Provost, in the Council Chambers, for the purpose of having an interview with the Right Hon. E. Cardwell, President of the Board of Trade, on the subject of having a Museum of Practical Geology established in that city. The Lord Provost introduced the business of the meeting by stating that as it was understood Government intended to establish a School of Practical Geology in Scotland, it was most desirable to have it founded in Glasgow, which was the centre of the mineral districts and manufacturing industry in Scotland, where it would be found practically useful, instead of being scientifically ornamental, which it would be if established in Edinburgh. Mr. Wm. Murray of Monklands, in urging the claims of Glasgow, stated, that situated as it was in the centre of the mineral dis-

trict, comprising the counties of Lanark, Ayr, Renfrew, and Dumbarton—a district inhabited by a third of the entire population of Scotland; producing 600,000 tons of iron annually, whilst all the rest of Scotland yields only 54,000 tons; and employing 20,000 persons in the manufacture of pig-iron, 8,000 more in converting into malleable iron, 15,000 in making it into ships, and other 15,000 in constructing engines and machinery on the Clyde—no other city could put in a claim for the foundation of the museum, which could bear a moment's comparison with it. Sir James Anderson, Mr. Hastie, M.P., and other gentlemen, having also enforced the claims of Glasgow, Mr. Cardwell rose and said, that there were two questions to be considered. The first was, shall the public money be devoted to the establishment of such an institution; and if so, in what part of Scotland should it be placed? It gives me pleasure to hear the statements of so many eminent men in Glasgow, and it belongs to me, in the department of the Government in which I am placed, to consider all such questions; but you are aware that it requires the sanction of that department which regulates the expenditure of the public money, before I can determine the question. All I can say is, that I have listened attentively to the statements which have just been made, both as to the necessity of such an institution, and the place where it should be situated, and that the subject shall be very carefully considered by me.

THE LATE D. M. MOIR ("DELTA"). It is with much pleasure that we are able to state that the name of the widow of Mr. D. M. Moir, surgeon, of Musselburgh—so well and widely known in the world of letters for the tale of Mansie Wauch, and other valuable contributions to literature—has been submitted to the Queen by the Earl of Aberdeen for a pension of a hundred pounds a year, and that Her Majesty has been pleased to approve of the Premier's recommendation.

EPIDEMIOLOGICAL SOCIETY. The Cholera Committee appointed by this Society are understood to be diligently engaged in investigating the origin and progress of the present outbreak of Cholera in the country.

PHYSIC FOR BRUTES. A hair of the dog that bit you is recommended as a cure for the consequences of drunkenness; but when intoxication results in beating women, the dog does not afford so proper a remedy as the cat. *Punch.*

A line contains ten words, so that any one can calculate the cost of an Advertisement.

Advertisements ought to be delivered at the office on the Wednesday preceding publication, and paid for at the same time.

Post-Office orders are to be made payable to THOMAS JOHN HONEYMAN, 37, Great Queen Street, Lincoln's Inn Fields, London.

LOST AND FOUND. We are requested by Mr. Michael to state that a lens belonging to a microscope was *lost*, and a pair of gold spectacles *found* at the place of meeting at Swansea.

DR. CHRISTISON ON GALVANISM IN CONSTIPATION. We regret to find that at p. 801 we copied a misprint from a cotemporary. The word *arms* is printed in place of *anus*. The sentence ought to read thus:—"the first way of using it was by directing the galvanic current from the mouth to the anus."

THE MEDICAL SCHOOLS. In compliance with the wishes of several correspondents, we propose, on the 23rd September, to give, in the body of the Journal, a condensed view of the prospectuses of the various medical schools which have appeared in our advertising columns, or which may appear on or before that date.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

MEDICAL ATTENDANCE ON SICK-CLUBS.

UPON several recent occasions, the attention of our readers has been directed, both by ourselves and by our correspondents, to the subject of sick clubs as they affect the interests of medical men. We again recur to the topic, not only because these institutions are in themselves the source of much injury to the medical profession, but especially because they are a part of that system of imposition and oppression, to which we are all more or less exposed, whereby our time, our skill, nay, almost our lives, are assumed to be at the disposal of the public (from government downwards), whenever they are asked for under the names of charity and benevolence. We deny not the claims upon our charity and benevolence; and we rejoice to bear testimony to the general readiness with which those claims are practically acknowledged by our professional brethren; but we do deny the right of any one, whether in a public or private capacity, to make them a ground of imposition in what ought to be purely business arrangements. We object to the abuse of the sacred name of charity, when it is improperly used to give an appearance of goodness to the gratuitous or semi-gratuitous services of medical men. How many, we ask, of the gratis morning levees of the unpaid dispensary and hospital officers, with their indiscriminate admission of patients, are held for the sake of true charity? We need not give the answer; all know it: all know, too, and feel, that reform of these things there must be—a reform which can only be brought about by earnest and united action. No body of men in our profession possesses the same power of acting in union as our own Association. To its members, therefore, we address ourselves, hoping that the reform, when once begun by them, will not cease till all abuses have been swept away.

Owing to the great variety of circumstances under which Sick Clubs are constituted; owing, also, to the great variation in the amount per member paid to the surgeons, it is impossible to form any calculation of the general remunerative value of clubs. Assuming, however, that from three to four shillings per member is the average annual payment,

and knowing that the ascertained average cost of the medicines for each patient treated in a public hospital is a little above four shillings, it is evident, as only a certain percentage of the members of a club are ill in the course of one year, that the payments made to the surgeon must cover the cost of drugs, and leave at least some margin of remuneration for time, trouble, and skill. Now repudiating any system of medical remuneration based, either actually or ostensibly, upon the sale of medicines prescribed, our calculation has simply to do with the amount of remuneration left after the actual cost of the drugs has been deducted. That such amount of remuneration is small enough even in the best paying clubs, there can be no question; but, whatever it may be, if it is what the members of the club can be justly expected to afford, it can never be derogatory to any medical man to accept it, if it suit his convenience to do so. Its acceptance is simply a personal matter, a calculation between value received and value of time given; and often, in the country, of the facility with which the members of a club can be attended coincidentally with the private patients of the district.

But, after private considerations, every medical man, as a member of the profession, has public considerations due to that body, in the acceptance of any public appointment. He is bound to take care that his acceptance of such appointment does not involve injustice to his medical brethren. Every practitioner who, upon the ordinary club terms, accepts clubs composed, either in whole or in part, of members who are able to discharge a reasonable medical account, clearly does so to the injury of his brethren and of himself: he withdraws individuals from the ranks of those who, consistently with the order of society, ought to do their part in the support of the profession as a whole. If persons who unjustly seek for club medical relief do not feel the degradation which they ought to feel in accepting the semi-charity of terms adapted to the scanty earnings of the labourer, medical men have no right to degrade themselves and the entire body of the profession, by pandering to such meanness. In confirmation of our sentiments, we cannot do better than quote from the extract from the *Union Médicale*, given in the Journal for September 2.

"But if we have some right to pride ourselves on our acts of charity, is it not our duty to take care that they are properly recompensed by those who can do so? And would it not be at once a dereliction of our duty to our brethren, and a lowering of professional dignity, to accept a position which would oblige a practitioner to visit the rich as well as the poor members of a club, thus depriving his brethren of a practice from which they could obtain some reward for their trouble, and throwing away his own services, as if he doubted whether they were worth anything?"

It is upon the established practitioner of moderate income and moderate practice that the abuses of the club system press most severely; encouraged as those abuses are, on the one hand, by young men struggling into practice, and on the other by men of large and old established busi-

ness, who employ assistants to do their club and union practice. By the former, the *respectable* club patient is hailed as likely to bring the more profitable accession of his family connexions; by the latter, the question of profit or loss is swamped in the generalities of a large income. To the established practitioner, with but a small or moderate practice, this question of profit and loss is a very different matter; to him, every private patient, who can pay his accounts, is a matter of consequence and calculation, and his withdrawal into the club ranks is a loss to be felt. Yet how difficult is the position of the medical man! If he resists what he knows and feels is an imposition and a wrong, he almost certainly risks the loss, not only of the one patient, but of the family. Need we feel surprised that, making up his mind that the first loss is the least, he succumbs to the force of circumstances, and certifies his *respectable* patient as a fit member for semi-gratuitous attendance?

We cannot blame poor men who act thus—men who feel they cannot afford to lose even an inch of ground in the battle of life; but we do blame the indifferent or aggrandising spirit of the independent men—the men of large practices and visiting assistants—who might rectify the evil, who might, without hurt to themselves, or rather to those dependent upon them, take an independent course, but who prefer permitting, and even aiding, the victimisation of their less fortunately placed brethren. To those who are in easy circumstances we appeal for co-operation in our attempts to remedy an evil which, though it may not affect their pecuniary interests, does affect their position as medical men, and originates calamities which press with severity upon others. Charity begins at home. Every medical practitioner, be his position what it may, is bound to see that, in exercising his vocation for the good of the public, he inflict not injury upon his own profession. Is it not the abuse of gratuitous advice, and of semi-gratuitous advice, which renders our Benevolent Fund and our Benevolent College so necessary?

WHERE OUGHT I TO INSURE MY LIFE?

WHERE ought I to insure my life? is a question which is daily addressed to medical men by some of their patients; and we fear that, too often, an answer is inconsiderately given. It does not follow that, because an insurance company promises to remunerate the medical profession, it is a safe and respectable concern; and as some seem to act as if this were the case, we think it our duty to caution our readers against too easily lending their names and influence to new and plausible speculations.

In our number for the 9th current, we inserted a letter from Mr. Henry Terry, jun., of Northampton, regarding a society which we find has been extensively advertised, especially in the provincial newspapers, under the name of the "New Economic Life Assurance and Loan Association". The advertisements represent the following gentlemen as trustees: Matthew Faber, Esq.; Alexander Peter Fletcher, Esq.; Ambrose Lockett, Esq.; William Pincher, Esq. We have made diligent inquiry among our City friends; and we find that these trustees are wholly unknown in the commercial world. As their addresses are not given in the prospectuses and advertisements of the company, we much fear that their standing as monied men is no better

than that of the directors of a more celebrated undertaking—the Glen Mutchkin Railway. If we are speaking wrongfully of these gentlemen, they have themselves only to blame; inasmuch as "William Deacon", their Secretary, who signs their prospectuses "by order of the board", has evaporated from the offices, 12, Took's Court, Chancery Lane, and has left neither man, woman, boy, nor placard behind, to tell of his own habitat or of that of the trustees. The affair is, or is not, a swindle; and we call upon Mr. Deacon and his friends to come forth from their hiding places, to gratify our curiosity on this subject.

It is not Mr. Terry's patient alone who has suffered; we are in possession of other cases of the same description. Mr. John Salusbury, of Conway, North Wales, informs us of a friend of his, who was treated exactly in the same way. The lady, who lives near Conway, in reply to inquiries which she instituted in London regarding the company, received the following reply:—

"Red Lion Square, Aug. 27th, 1853.

"MADAM,—By Mr. ———'s direction, I have made inquiries in Took's Court respecting the New Economic Life Assurance Company, and regret to inform you that it is a complete swindle. The parties left there last Monday, without paying the rent of the room occupied by them as offices: since which time many applications have been made by parties, who, like yourself, have been duped; but at present nothing has been heard as to where they have gone to.

"I am, Madam, your obedient servant,

"H. E. HINGTON."

There are other insurance companies, regarding which we may yet be obliged to make some remarks. But in the meantime we forbear, in the hope that, during the next session of Parliament, an Insurance Company Registration Act will be passed, which will effectually keep sharpers out of the field. At present we would say, that when a medical man recommends an office, he ought to feel morally certain of its solvency and respectability; and he ought to bear in mind that some of the new companies are most hazardous ventures.

ORIGINAL COMMUNICATIONS.

ON FEMALE STERILITY, WITH SOME PRACTICAL SUGGESTIONS FOR ITS REMOVAL.

By WILLIAM BAYES, M.D., one of the Physicians to the Brighton Dispensary.

It is interesting in the outset of our inquiry to glance at the laws which appear to govern the increase of the human race. Viewed as a whole, the population of the world appears rapidly on the increase. There is no fear of depopulation from any natural causes with which we are at present acquainted. But a marked difference in the ratio of increase appears, if we contrast particular countries and separate races of men.

The increase is most apparent in the temperate regions, from this cause, that the average duration of life is longer than in those regions where extremes of heat or cold predominate.

In newly discovered, yet fruitful countries, human fertility is very great; it is less where population is dense.

where civilisation has reached a high pitch. Again, human fertility is great among a well fed and well clothed labouring population. It is less among the idle and luxurious.

These two examples, however, are in reality identical, since in all newly discovered, sparsely populated countries, the inhabitants necessarily belong to the labouring class, and to the most healthful of that class, viz., the agricultural. And lastly, fecundity is great among new nations composed of various elements and of a mixed population, while it is much less in the older nations, especially where, from natural or artificial restrictions, they are much confined within their own limits, and remain almost unmixed.

But our inquiry does not relate to the fertility or sterility of nations; at present there is more fear, in Europe at least, of over population, than of the reverse; and even if that were not the case, it would more properly belong to the province of the political economist than of the physician. It is with individual cases we have to deal, where it occasionally happens that the greatest grief and distress are consequent upon sterility; and it is with a view of inquiring how far the causes of this sterility are removable by medical interference, that I have penned these few lines.

Descending, then, from communities to individuals, we shall find that where both the man and the woman show fine physical development, and are possessed of a sanguine temperament (which must be looked upon as the true index of perfect health and vigour), their families, *ceteris paribus*, will be both numerous and healthy. And further pursuing our inquiry, we shall find that the woman who has a broad well shaped pelvis, and a good bust, together with fine muscular development, and a rounded contour, will bear the largest number of children.* In other words we would say, that where the body is finely formed, where every part is well expanded, where the mind possesses a happy and quiet disposition, where an equable balance is preserved between the animal and mental powers, there will be force, regularity, and rhythm of every action, and in the performance of every function, and there will exist the most happy state for fertilisation. Whatever detracts from this state of body in either the male or female, must be considered as antagonistic to fertility, and as tending to sterility. This faulty organisation is far more frequently to be found in the female than in the male sex.

The artificial life led by the luxurious and highly civilized among the upper classes tends to a loss of balance between the animal and mental powers; it tends to exaltation of the functions of the sensory and depression of those of the motor tracts of the nervous system (bodily), and to a preponderance of the sensations, feelings, and passions, over the reasoning powers (mentally).

Thus, in place of expansion, we find contraction of the frame, flattened chests, curved spines, and narrow or distorted pelvis. We find a loss of balance in the muscular power. Its contractions are partial, spasmodic, and intermittent, in place of rhythmical and tonic. Or, on the other hand, a general relaxation of the fibre occurs, allowing engorgement of the lymphatics, as in the scrofulous. And these same states of body have their psychical analogues in the alternate excitability and listlessness of the mental efforts.

Faults in the organisation, such as these, are of course most readily combated and corrected during youth; yet even in riper years it is astonishing to find how much the general development may be expanded by perseverance in judicious measures.

Proceeding in our subject to the more immediate causes of sterility in the female, which are likely to be benefited by medical interference, we should divide them into three classes.

- I. Mechanical;
- II. Functional; and
- III. Moral.

I. MECHANICAL CAUSES. With regard to the first, I shall not here speak at length, since it must be obvious that where a mechanical obstacle exists, it must be removed before impregnation can occur.

The most frequent obstacles are uterine displacements, prolapsus, retroversion, anteversion, etc., and a narrowness in the passage through the os and cervix, sometimes almost amounting to stricture. Also, occasionally imperforate hymen and a contracted state of the vagina, allowing of only partial connexion. So far as my own experience goes, uterine displacements are of increasing frequency. In the majority of cases, sterility, arising from these causes, is capable of cure, if advice be sought early, and the cause be discovered.

II. FUNCTIONAL CAUSES may be subdivided into—

- A. An irritable state of the uterus, constantly tending to produce clonic spasm, and causing dysmenorrhœa.
- B. The atonic state, which is usually accompanied by leucorrhœa.

Whether the dysmenorrhœa arises from an unnaturally acrid state of the menstrual fluid causing irritability of the uterus, or whether the womb itself is at fault from hypersensibility, from ulceration of the os, or from its passage being preternaturally contracted, we cannot look for impregnation, until this morbidly irritable state of the organ is subdued. If the quality of the blood be hyperæmic or anæmic, we must correct it. If local irritability be present, we must search for its cause, and subdue it.

In some cases, this is not a matter of much difficulty. It often depends in the newly married on local excitement, and will give way readily on the temporary suspension of intercourse. In other cases, as where ulceration of the os uteri exists, it may be more or less difficult of removal. But there are other cases, where, in spite of all the means at present in general use, dysmenorrhœa still continues; and although during the intervals the health may apparently be perfect, no sooner does the time approach, than the warning pains are felt, and hours or days of pain and illness must be again endured.

Where this is the case in young females, it sometimes happens, if they marry early in life, that they soon become pregnant; and if they escape miscarriage, their subsequent menstrual periods recur, after weaning the infant, with little or no pain. But although this occasionally happens, such a happy termination is by no means frequent, especially when the dysmenorrhœa has been of long standing, and where the female marries later in life. In these it would appear as though the habit of body were too strongly grafted upon the system to be easily checked; so that although a few days, or even a few weeks, beyond the usual period, may occasionally elapse, and hopes be thus excited, yet the uterus is still so irritable, that it will not tolerate even the slightest distension, and the discharge returns with twofold violence, adding another and recurring cause of sterility in the frequent disappointments hence ensuing.

If we assume, as a physiological fact, that each menstrual period is analogous to the "heat" of animals (and this is the most recent view), and that each catamenial discharge is accompanied by the expulsion of an ovum, which having become matured, has failed to be fertilised, and is thus cast out of the body; we must then suppose that the most fortunate period for impregnation is the moment when the ovum is ready to drop from the ovarium; just as the most fortunate moment to prepare the ground round a tree for the reception of its seed is at the very moment when the ripe fruit is ready to fall. But in the functional derangement, now under our consideration, the difficulty lies in this, that the uterus is so irritable that its tendency is, not to retain but to expel.

Our inquiry here will be, Can this expulsive action be reversed? I do not hesitate to say that in very many cases it can. And the consideration of the means I would suggest leads us to some very interesting points for investigation.

* Narrowness and contraction of the pelvis is the sign of a worn out race, both in man and in woman.

In severe cases of dysmenorrhœa, the pain is not only to be found in the lumbar, sacral, pubic, and iliac regions, but extends down the inner part of the thighs, and often in the mammae.

In some cases of amenorrhœa, a vicarious discharge has flowed from the breasts.

The great and marvellous sympathy between the mammae and uterus is well known to every practical physician. As a means of arresting uterine hæmorrhage after labour, the application of the infant to the breast has long been known and acted on. Here appears the most powerful example of the direct sympathy of distant organs, and of the diversion of the circulating fluid from one portion of the body to another. In a less striking form the same occurs during lactation, the menstrual flow being suspended during suckling. In other words, the uterus remains quiescent when the mammae are in a state of activity.

It is needless to enlarge on points so well known to practical observers: enough has been said to illustrate my meaning. I would suggest whether the consideration of these facts does not point out to us an easy and safe channel, through which not only to alleviate the pains of those who suffer from dysmenorrhœa, but also show us a means by which the womb may be made to pause, and its morbid irritability be moderated sufficiently to allow of successful impregnation.

Dr. Marshall Hall has proposed that a strong infant should be applied to the breast with this double view: but it seems to me that, apart from the inconveniences and practical difficulties attending such a course, there are other means which would prove even more serviceable. My own suggestions would be, that fomentations of warm milk should be used to the breasts a day or two before the expected period; that a breast pump should be gently applied at the same time for a quarter of an hour, two or three times during the day; that the space from the last cervical to the eighth or tenth dorsal vertebræ, for some inches on either side of the spine, should be kept warm with hot flannels; and that the apartment should be kept warm and well ventilated. These means should be continued until the period has fully arrived. If the menstrual flow then appears, the warmth thus applied need not interfere with other means, supposing the pain to be severe. If intercourse shall have taken place and conception have followed, I should suggest the continuance of the fomentations until the period over which the catamenia usually extend shall have passed. Presuming, as is most likely to happen, that the first application of these means fails in immediately inducing conception, it will still have made a step towards it by lessening the irritability of the uterus. During the interval between the catamenial periods, I should now suggest a temporary absence from home; and that abundant exercise, a full exposure to the open air, freedom from mental occupation, and every measure tending to produce muscular strength should be adopted, while intercourse should be avoided until a few days previously to the next period, when a recurrence of the same means should ensue. The development of the mammae should also be favoured by carefully protecting them from cold, and by occasional friction with a soft hand and a little warmed oil or milk.*

Sterility may ensue from general hyperæmia or anæmia, and it is often strange to notice how immediately fertile the uterine system becomes, after the removal of these adverse states. The former is not unfrequently met with in the upper classes of society, where food of the most nutritious and rich kind is abundantly partaken of, and where wines are freely taken, whilst the amount of exercise and exposure to vicissitudes of temperature is extremely small. In these cases, the uterine loss offers a safeguard to the general health, and profuse menstruation becomes a habit needful

to the preservation of life. Fertilisation, here, can only take place when a simpler diet is substituted, and muscular exertion to some extent persevered in, so that the uterus is allowed to return to its simpler and more natural duties. An anæmic condition, sometimes accompanied by amenorrhœa, generally with deficient and painful menstruation, and not unfrequently with profuse leucorrhœa, is also one of the causes of sterility. Iron and generous living here suggest themselves, but especially out door exercise, as much as can be borne. The cold douche to the lumbar region is among the most powerful of the tonic means at our disposal. Cases of this kind very frequently present themselves to our notice, in which we see conception occur almost immediately on the removal of this condition.

III. MORAL CAUSES. Before concluding we must glance, though cursorily, at the moral causes. Some pernicious habits in which the young occasionally indulge, often in ignorance of the evil consequences they are certain to entail, lead to sterility, through their debilitating effects upon the constitution. These and their remedies need not here be entered upon. But there are other moral causes which are apt to be overlooked, and which are connected with modern education and civilisation, which tend to induce a passive and enervated condition of body in our females, very adverse to the free development of the frame. These act indirectly by lowering the standard of the general health, and thus tend to produce the evils just mentioned. The whole education of an accomplished girl tends to a repression of the natural feelings, and teaches her to hide every expression of her natural impulses, by word or look. Hence, all instinct becomes blunted and suppressed, and she even gets to look upon that which is legitimate as something immodest and indelicate. This retiring and shrinking bashfulness is not consonant with conception. The lower classes of society, less refined in their feelings, unaccustomed to their suppression, meet the advances from which the other retires, and thus become easily fertilised. But it is otherwise with the highly civilised and, so to say, etherealised child of art; and nature here abandons in her turn her who has despised and thwarted her lessons and her hints.

Marine Square, Brighton, Sept. 1853.

[We conceive that there is either dangerous error or much ambiguity in the concluding paragraph of this interesting paper. As the physician seeks his examples of female fertility and health among rustic home-bred women, and not among the "accomplished girls" of fashionable life, so does the poet and the man associate the beauty of a blush with untutored simplicity, and not with the perfection of an accomplishment. We cannot, therefore, avoid stating our conviction, that it is an error both in morals and in hygienics, to regard "shrinking bashfulness" as, under any circumstances, a cause of sterility; and that it is equally incorrect to regard *genuine* "shrinking bashfulness"—the most charming attribute of woman—as the real or generally alleged characteristic of "the etherealised child of art".—EDITOR.]

CANCER OF THE SIGMOID FLEXURE OF THE COLON AND FIRST PART OF THE RECTUM: DEATH FROM PERFORATION.

By C. E. REEVES, B.A., M.D., &c.

CASE. M., aged 78, tall and still somewhat muscular, with dark eyes and grey hair, had been treated by a practitioner for piles and indigestion for some months. The history of his case, as near as it could be obtained, from his being deaf and the fatigue which talking produced, was, that during the last eight months he had gradually lost flesh and strength; his bowels, always constipated, had become more and more acting without powerful purgatives. Four months before his first experienced tenesmus: this had gone on, and he had

* In the application of the fomentations, Markwick's spongio-piline offers a very useful material; and if a circular piece be perforated at its centre with a hole for the nipple, and a V shaped portion be cut from the centre, it can be made to fit the breast perfectly.

severity, particularly towards evening, and had obliged him to get out of bed ten or twelve times in the course of the night. During this time, the evacuations obtained by purgatives, such as croton oil, had been very scanty, consisting of slimy matter mixed with a little fluid feces and occasionally a little blood. He had suffered throughout much from flatulent eructations, attended with burning heat at the epigastrium.

His skin was pale, with an almost imperceptible tinge of yellow, bearing a close resemblance to badly bleached white wax; his conjunctivæ were clear and bright; pulse good; the appetite during the last fourteen days had been failing, and now any attempt to take food excited nausea.

The abdomen was rather large: on the right side the descending portion of the colon could be distinctly felt, containing large masses of feces down as low as the sigmoid flexure; the ascending and transverse portions were dull on percussion, and undefinable, from the small intestines being equally distended with fluid. The stomach was empty; the liver was normal, situated rather high, but the gall-bladder projected beyond its lower margin nearly three-quarters of an inch, and felt hard and resisting. On introducing the finger into the rectum, a hard scirrroid body was felt two and a half inches up, larger posteriorly than anteriorly and laterally, with a small opening in it just admitting the apex of the index finger. He had slight lancinating or pricking in this region, but the tenesmus was the most troublesome symptom. The motion which had been passed a short time before, consisted of about three tablespoonfuls of fluid feces, with two or three small clots of dark coloured blood, and two masses of the size of large peas of dirty ashy coloured muco-purulent matter. This matter, on being examined under the microscope, gave indication of cancer-cells. The motion had a peculiar putrid fishy smell. The symptoms continued much the same until the third day before death, when considerable tenderness was complained of over the descending colon. His pulse rose from 72 to 80; his tongue became brown, and he was unable to take anything. The tenderness was much mitigated by the next day by the application of cold water; yet the pulse had risen to 100, and this day, in addition to the evacuation of fecal matter, he had passed between five and six ounces of foetid serum tinged with blood. He had also vomited several times very dark greenish foetid fishy watery fluid, with flaky masses in it, like those seen in the motions. On standing, the flaky masses sank with a dark green substance, like inspissated bile, to the bottom, leaving a rather clear fluid, like cabbage water. On the morning of the day of his death, the tenderness over the descending colon had nearly subsided, the masses of feces were more moveable, and they seemed to be now floating in fluid. The vomiting had continued. An evacuation from the bowels had been preserved; it consisted of about a tablespoonful of fluid feces with streaks of dark coloured blood. Pulse 116.

At half-past twelve A.M., he began to complain of pain in the bowels; and he passed nearly a quart of fluid feces, mixed with streaks of dark coloured blood. The pain in the abdomen increased in severity, and, when seen two hours from its commencement, he was suffering the most excruciating agony, pulseless, and nearly speechless, with yellow watery bilious matter rising up into his mouth every few minutes. It was only after 160 drops of tincture of opium had been given, in three doses, at intervals of ten minutes, that any relief was obtained, and his pulse became at all perceptible. He sank at 6 P.M.

POST MORTEM EXAMINATION, sixteen hours after death. The abdomen was not distended, but the peritoneum, on being incised, gave issue to some highly foetid gas. The intestines were covered with fluid fecal matter, which was seen to ooze from between the pelvic viscera on the slightest pressure, or on moving the body. The descending colon was felt largely distended with fluid, in which floated two large masses of fecal matter, each the size of a fist. Several dark violet coloured patches of congestion, varying in size from a shilling to a florin-

piece, existed on the peritoneal membrane; some patches of the same character were present on the small intestines, larger in size, but much less intense in colour. The capillaries of the peritoneum of the abdominal wall were injected; this injected state increased considerably towards the dorsal region. On separating the small intestines from the pelvis, some flakes of dirty muco-purulent matter were seen, and, on pressure, fluid feces issued from the right side of the sigmoid flexure of the colon, from an irregular jagged opening; but the parts were so exceedingly soft, that its magnitude could not be well determined, and it was with the greatest difficulty that they were removed for inspection. The whole of the walls of the sigmoid flexure were scirrroid, varying in thickness from a quarter to half an inch, of a fibrous character, and easily broken down. On the anterior part, near the centre, an irregular excavated ulcer existed, about three inches in diameter, covered with the same kind of dirty muco-purulent fluid as was seen in the pelvis, and had been passed during life. To the right of this ulcer, a kind of sinus existed; and here the intestine seemed to have given way. The mucous membrane throughout was glistening, with a thin deposit of melanoid substance in its submucous tissue; this extended down to within three quarters of an inch of the termination of the rectum, not abruptly, but in a kind of fringe-like manner. Some of the mesenteric glands were melanotic, and also those along Glisson's capsule.

The liver was of the ordinary size, but situated high up. It was of a black colour, with a slight tinge of green; and soft, breaking down with very slight pressure; its coverings were easily removed; the granules were much larger in the superior than in the inferior part. This layer of black extended uniformly all over the organ, to the extent throughout of one-sixth of an inch; and the granules, although easily seen by breaking it, were yet smaller, and seemed more compact, than in any other part of the organ. I regret that the inadvertence of a servant, in throwing away the parts of the diseased colon and liver which I had brought home, prevents me from giving their microscopical characters. While making the examination, I applied a little salt to the dark layer of the liver; and, in the course of a few minutes, it changed the colour to a beautiful dark grass green.

The gall-bladder was very large and tense; oval in shape; three inches in length, and two inches in diameter near its centre; thickest at its inferior part. Half an inch from the extremity a slight indentation existed, the remaining portion curling upwards over the free margin of the liver. In its neck a small oval stone was found impacted, preventing bile from passing into the duct. Cut open, it was found to contain about two ounces of nearly clear coloured fluid, somewhat thick and viscid, like oil. The application of heat immediately coagulated it. The internal surface was quite smooth. The gall-stone was of the size of a small marble, ovoid in shape, rough and glistening, lighter than water, yellow on one side, and dark on the other. It was impacted in a pouch immediately external to the neck of the bladder. It seemed as if the stone had consisted originally of inspissated bile, and had become arrested; and that the deposit of clear cholesterine had taken place, until at last the duct had become quite blocked up. The dark portion of the stone, where it was in contact with the sac, had tinged it of a dark colour. The cystic duct was large, and would with ease admit the thick end of the blow-pipe. The spiral apparatus was obliterated, and it was tinged with bile to within a quarter of an inch of the cyst which contained the stone. The hepatic duct was also much larger than usual; but this and the other biliary canals were quite free. The stone, on section, consisted of two portions—a dark, forming three-fourths, consisting of inspissated bile, with a little cholesterine; the remaining part consisting of cholesterine. All the other viscera were healthy.

Harrington Square, London, Sept. 7, 1853.

CASES ILLUSTRATIVE OF THE TREATMENT OF SOME VARIETIES OF CHRONIC RHEUMATISM.

By C. HANDFIELD JONES, M.D., Senior Assistant Physician to St. Mary's Hospital.

THE following cases of diseased action depending upon rheumatism seem of sufficient interest to be worth recording, if only as memoranda of well marked instances of disease, and of the action of remedies. The brief way in which they are reported was unavoidable, as they all occurred in hospital out-patients, and time was of course wanting to make detailed inquiries.

CASE I. Jane F., aged 6, residing at Kensal Green, was admitted on Feb. 9th. She had a kind of fit, her mother stated, six weeks previously; but she did not lose her consciousness. At present, she was stupefied several times in the course of the day. She had pain in different parts of the head, which was not increased at night. The tongue was clean; the urine clear. She was living on the bank of a canal, in a damp place. The following medicine was ordered:

R Potassii iodidi 3 ss.
Liquoris potassæ 3 iss.
Infusi calumbæ 3ij. M.

Sumat 3ss. ter die.

Feb. 16th. She was decidedly better this week than last; but made a groaning dismal noise in her sleep, much more some nights than others. The medicines were continued.

Feb. 23rd. She was not free from fits, but had them certainly less often. Her mother said that when she was affected, she could compare her "to nothing so much as to a tipsy man in his foolish talk". The bowels were properly open; the pulse weak. The head was tender; she could not bear to have it touched. A blister was ordered to be applied to the neck.

R Ferri carbonatis gr. x. ter die.

March 1st. She had had no fit since the blister; but had one sharp attack on the night on which it was applied.

March 8th. She had no more fits, but rambled and talked during the night. The bowels were confined.

R Syrupi ferri iodidi 3ij.

Aquæ 3iss. M.

Sumat 3ss. ter die.

R Hydrargyri c. cretâ gr. iij.

Pulveris jalapæ gr. v.

Fiat pulvis alternis noctibus sumendus ad tres vices.

March 15th. She was improving; and did not talk so much during the night. The medicine was continued.

March 22nd. She had now quite lost all her former symptoms, and rested better at night.

April 5th. She was quite recovered, and gone to school.

REMARKS. That the pain in the head, and the cerebral disturbance, in this case, were occasioned by the action of the rheumatic poison seems pretty certain, from the nature of the pain, the tenderness of the scalp, the general progress of the disorder, the damp nature of the residence, and from the *juvantia*. The influence of local treatment was shewn in the good effects of a blister. Disturbance of the cerebral functions is by no means common, as the result of chronic rheumatism. Neither Dr. Copland nor Dr. Fuller makes mention of it. Had this affection continued longer, the chronic inflammatory action would, it is very probable, have produced hypertrophic thickening of the cranial bones, and a roughened state of their internal surface; and then the disorder would have become well nigh incurable. A female has been more than once under my care, in whom repeated rheumatic attacks, of the same chronic character, seem to have been the cause of imperfect speech and giddiness, with impairment of voluntary and mental power, from which she can obtain no relief.

CASE II. P., female, aged 1½ year, came under my care on May 10th. Her mother described her as a backward child. She had no teeth, and was frequently ailing. The

tongue was not coated; the bowels were in good order. The anterior fontanelle was depressed. The skin was in the morning cool. The child was very feverish and restless at night, becoming worse about 4 P.M.; constantly crying and moaning, very fractious and restless, rolling her head about. The feet were always swollen at night. The head, at the time of examination, was not hot. She had been ill five days. She lived in a healthy place.

R Potassii iodidi gr. ix.
Liquoris potassæ 3 ss.
Vini ipecacuan. 3 ss.
Aquæ anethi 3ix. M.

Sumat 3j. ter die.

May 15th. She had had two good nights; complained much less of the head, and was evidently much better; but had no appetite. The mixture was continued; and a teaspoonful of cod-liver oil was given three times a day.

June 30th. The mother called on me for another purpose, and told me on inquiry that the child had quite recovered from her former symptoms, and had thriven much better.

REMARKS. There was a good deal of apparent resemblance in this case at first to more serious disease; it might easily have been taken for a case of meningitis. However, the depressed state of the fontanelle, the nocturnal exacerbation, the swelling of the feet at night, and the absence of fever and of gastric disturbance, made it probable that the distress of the head was owing to a different cause. The beneficial influence of antirheumatic treatment was very apparent.

CASE III. W. W., aged 28, a cabman, was admitted on March 8th. He had had severe pain at the back of the head during two months. It was felt mostly at night, and had probably been brought on by damp. There was no disturbance of functions.

Tincturæ cinchonæ 3j.
Decocti cinchonæ 3j.

Fiat haustus ter die sumendus.

March 22nd. He was much better.

April 5th. He had quite recovered; but seemed to want a tonic. He was discharged with directions to continue the same mixture, without the iodide of potassium, for a few days.

REMARKS. This was a typical case of rheumatic neuralgia cured by iodide of potassium. The man continued his occupation of cab driving all the time.

CASE IV. E. P., aged 32, wife of an omnibus conductor, was admitted Oct. 9th. She was suffering from frontal headache, which was increased by the recumbent position. The head was tender to the touch. She often had pain in the ancles. Her sleep was broken. The bowels were costive; the tongue was slightly coated; the urine scalded, and was high coloured. She felt very weak.

R Potassii iodidi gr. iij.
Potassæ bicarbon. 8j.
Decocti aloes comp.
Infusi calumbæ, aa 3ss. M.

Fiat haustus ter die sumendus.

Oct. 20th. She was better. The legs were free from pain. The urine was clear, and did not scald. The draught was continued, with the addition of five minims of tincture of cannabis Indica.

Nov. 10th. She went into the country soon after the last report, and returned with the same symptoms. She was ordered to resume the medicine.

Nov. 17th. She complained of itching all over, and some pain at the top of the head. The other pain was less. The draught was continued, the tincture of Indian hemp being omitted.

Dec. 1st. The itching continued in some degree. She was directed to take a mixture of quinine with sulphate of iron three times a day; and four grains of compound aloetic pill at night.

Dec. 15th. She was stronger, but still felt rheumatic pains occasionally.

Dec. 29th. She was going on very well, and felt "quite a different person". She was ordered to continue the medicine for a week.

REMARKS. The rheumatic symptoms in this case were very marked, amounting at first almost to subcutaneous. After being relieved by the employment of iodide of potassium and alkalis, they persisted for some time in a less degree, and were finally removed by the tonic action of quinine and iron. It seems questionable whether the itching was a rheumatic affection or not; it might be regarded as an hyperæsthesia: but no mention is made by Romberg of any such state resulting from the presence of the rheumatic poison in the blood. It is very conceivable that the *materies morbi* of rheumatism circulating in the capillaries might cause some irritation of the nerves in the papillæ, and so give rise to itching, much in the same way as occurs in jaundice.

CASE V. S. M., aged 33, a labourer, was admitted Feb. 16th. He had some short time ago an accident, which caused concussion of the brain; he was brought to the hospital, and, after remaining there several days, he was discharged. Very soon after this, he applied as an out-patient, complaining of severe pain at the left side of the head, extending up all over it. The pain was not constant; it was sometimes more severe at night, and sometimes by day. The patient was a stoutly built man, of rather sanguine aspect.

R Potassii iodidi gr. iv.
Liquoris potassæ ℥ss.
Decocti cinchonæ ʒiiss. M.

Fiat haustus ter die sumendus.

Feb. 23rd. He did not feel nearly so much pain as the preceding week. The medicine was continued.

March 1st. He had much pain at the back of the head on the left side, but slept well.

Sumat ferri carbonatis ʒj. ter die.

Opiate liniments were ordered to be applied.

March 8th. He was much better, but still had some remains of the occipital pains. The draught prescribed on February 16 was resumed.

March 15th. He was not so well. A blister was applied to the back of the neck; and the carbonate of iron was continued.

March 18th. He had less pain since the blister, but was not free from it.

Misturæ camphoræ ʒj. M.

Fiat haustus ter die sumendus.

March 22nd. He was much better. The medicine was continued.

March 29th. Colchicum was substituted by a friend, who saw him in my absence.

April 5th. The pain had returned, and had been much worse last week, principally on the left side.

R Potassii iodidi gr. v.
Sodæ sesquicarbonat. gr. v.
Decocti cinchonæ ʒj. M.

Fiat haustus ter die sumendus.

A blister was applied behind the ear.

April 10th. The pain increased during the first three days of the week, but was subsequently less. Five grains of iodide of potassium and a drachm of tincture of cinchona were added to the draught.

April 15th. The pain was remitting, but on the whole less severe. The pulse was very weak.

April 17th. The patient was ordered to take mixture of quinine with sulphate of iron three times a day; and half a grain of extract of belladonna three times a day.

April 22nd. He felt a great deal better, and had very little pain.

April 26th. He was in about the same state. The appetite was good; but his strength did not increase. The pulse was of rather better force. The decayed stump of the last molar tooth was found to be exciting irritation in the upper alveolar arch. The medicines were continued; and equal parts of creasote and laudanum were ordered to be applied to the decayed tooth.

May 5th. The head was almost entirely free from pain; but he had a little on the right side.

May 10th. He had no return of the pain in the head; and was discharged cured.

REMARKS. The previous concussion of the brain might have excited suspicion how far the pain of the head was merely neuralgic. Relief was soon obtained by the employment of iodide of potassium; but afterwards, even in much larger doses, it ceased to produce a good effect. Colchicum was not beneficial; and belladonna did not seem to be of any particular use. The quinine and iron were the most effective remedies. The man continued, I believe, at his work as a labourer; but the debility which he experienced was very manifest. This seems to be a common feature in these neuralgias.

CASE VI. W. B., aged 39, a compositor, was admitted September 16th. He had very recently been in the hospital, suffering from weakness and painful aching of the limbs: he went out nearly, but not quite recovered, and soon relapsed. He stated that he had formerly had gout. His right arm was now much affected. Iodide of potassium with bark was given thrice daily, and camphor with henbane at night. He was ordered to rub an opiate liniment on the part.

Sep. 20th. He said that he was improved, and that he slept better. The pains in the limbs were diminishing, but were brought on by exercise.

Sep. 27th. He was improving "nicely".

October 4th. He had been much better during the last week, the pains gradually decreasing.

October 21st. He had pain in both loins, and some weakness in the elbows and arms. The urine was not clear, and high coloured.

October 25th. The pain was much more severe in the arms and shoulder. The tongue was clear; the urine clear: his bowels were open.

R Syrupi ferri iodidi ʒj.
Potassii iodidi gr. viij.
Decocti cinchonæ ʒj. M.

Fiat haustus ter die sumendus.

October 25th. He was wonderfully better since taking the last medicine.

November 1st. He was improving much, but had no flannel, and was half starved. The medicine was continued.

November 4th. He had no pains in the arms, and felt very well, but had an abscess forming near the anus. On account of this, he was again admitted as an in-patient. It was opened, and discharged purulent matter for some time. He left the hospital November 23rd, and did not present himself as an out-patient.

REMARKS. The rheumatic nature of the affection in this patient was not at first apparent; it was not regarded as such during his first stay in the hospital. The effect of remedies, the occasional shifting of the pains to other parts, and

the condition of the urine on the 21st, when a relapse took place, seem to show pretty certainly that it had its origin in this most common cause. It is also very probable that the abscess in the nates was connected with the same constitutional state; that it became, in fact, a focus of eliminative action. I had at one time a case under my care in which the symptoms presented at the outset the appearance of rheumatic fever, but quietly changed to a typhoid state; while collections of matter continued to form for a long time in various parts of the limbs. The cause of this unusual change can only be sought for in some peculiar condition of the vital powers, in consequence of which a disposition to generate pus took place of that which ordinarily produces lactic acid, the received *materies morbi* of rheumatism.

CASE VII. M. A. S., aged 42, married, had rheumatic pains all over her. They were most severe in the hands. Her urine was generally high coloured, and deposited lithic acid. The tongue was smooth, clear, and moist. Her digestion was pretty good.

BIBLIOGRAPHICAL NOTICES.

PRACTICAL OBSERVATIONS ON AURAL SURGERY, AND THE NATURE AND TREATMENT OF DISEASES OF THE EAR. By WILLIAM R. WILDE. pp. 506. London: 1853.

WE have had much pleasure, and not a little profit, from the perusal of this very excellent work, which we have placed on our shelves beside other standard treatises, the works of good, clear-headed, observing men—not "specialists", but sound scientific practitioners, entitled to the confidence of the profession, and wholly devoid of quackery or puffing.

From the situation of the organ of hearing, and the comparative difficulty of investigating the morbid appearances it may present, it has been till lately one of our medical opprobria, and has fallen under the dominion of quacks, lay and medical, the latter of whom Mr. WILDE justly castigates in the "History of Aural Surgery" which forms the introduction to this book. He divides the history into three epochs, the first marked by the introduction of the speculum (Fabricius); the second, by the application of Eustachian catheterism (Cleland); and the third, by the operation of perforating the membrana tympani, in certain cases of deafness (Sir A. Cooper).

The second chapter of the work contains the means of Diagnosis of Diseases of the Ear, and the Mode of Applying Instruments. We have for several years been ourselves in the habit of employing the simple and convenient speculum recommended by Mr. Wilde; it is a polished conical silver tube, of such a size as to fit the meatus, and infinitely to be preferred to the complicated instruments which have been so much vaunted. It "should be made as light as possible, highly polished both inside and out, with a stout rim or brim round the larger margin, and the smaller aperture well rounded off, so as not to irritate the ear." The patient is to be placed opposite a window into which the sun is shining; and the membrana tympani can now be easily seen and examined. Lamp-light is to be discarded.

The stethoscope, applied over the ear, is useful in enabling the surgeon to appreciate the varieties of sound produced on driving air into the tympanum, either by an expiratory effort on the part of the patient, or through the Eustachian catheter. This last named instrument, Mr. Wilde considers, will be found much less frequently necessary than many fancy; and he raises his voice against introducing probes into the drum of the ear, and among its small bones. The Eustachian catheter which he recommends is much wider than those commonly seen, and is always to be introduced through the nostril; but he repeats that, when the patient is able to inflate the membrana tympani himself, or when the cavity is inflamed, catheterism of the tube should never be employed.

We have in this chapter some observations on tinnitus, and its various characters. These Mr. Wilde cannot connect with any special lesions of the apparatus of hearing; in fact, he thinks that the description which patients give of the noises in their ears depends mostly upon fancy; servants invariably stating that they suffer from "the ringing of bells"; while, in his country, old women usually sum up their complaints by saying that "all the kettles in Ireland are boiling in their ears". Our author states that the tincture of arnica has proved useful in some cases of tinnitus.

In leeching the ear, the animals should be made to bite close to the orifice, or just behind or in front of the lobe of

the ear. Galvanism and electricity Mr. Wilde discards from the catalogue of remedies. On the use of mercury, he gives some good, but rather diffuse observations: the same rules apply to its use in diseases of the ear as in those of the eye, and especial praise is justly bestowed on the alterative powers of corrosive sublimate.

Chapter III contains the Statistics and Nosology of Ear Diseases. From an analysis of 2,385 cases treated at the dispensary, it appears that diseases of the auricle and external meatus amount to nearly one-half of the entire; affections of the membrana tympani, exclusive of collapse, number 819, or nearly one-third of the whole; and diseases of the middle ear amount to 101, or about a twenty-third of the whole. A very minute register is given of 200 cases, taken without selection from the records; and "the state of the membrana tympani is the most valuable result afforded by the examination of these cases. In ten instances only it was found natural; so that such may fairly be stated as the proportion of cases of 'nervous deafness';" in the other cases, it presented a great variety of morbid appearances, being thickened, vascular, opaque, ulcerated, etc., as variously as the cornea is; and from these records, "as well as Mr. Toynbee's researches, it is incontrovertibly manifest that inflammatory affections of some form or other have been the chief cause of aural diseases". It is manifest how this conclusion ought to affect our practice. The chapter concludes by a nosological classification.

The author next enters upon the proper subject of his work, which, however, "does not profess to be a complete system of aural surgery, but is intended to supply the reader with a practical treatise on the most frequent and urgent affections of the organ of hearing". This object Mr. Wilde has very successfully accomplished; his descriptions and directions being, though somewhat diffuse and occasionally episodic, throughout correct, practical, and distinct.

The diseases of the external ear are first considered, preceded by a sketch of the anatomy of the parts; and similar short accounts of the structure introduce the maladies of the more internal parts in the subsequent chapters. In treating of wounds of the auricle, our author informs us, on the authority of Dr. Carter, that, whenever a negro in the West Indies wishes to attach to himself a dog, he nails its ear for a day to the door-post of his cabin. These dogs must be possessed of a curious idiosyncrasy—first, in respect of their moral affections being seated in the ears; and secondly, in that the feeling of attachment can be excited by a process which one would think more likely to stimulate the organ of combativeness to action.

There is a curious form of inflammation peculiar to insane persons, in which the auricle swells until, in some cases, the skin breaks, and the parts discharge thick dark coloured blood and serum.

Mr. Wilde describes six kinds of tumours found behind the ear: an irritable and painful tumour of the sterno-mastoid gland; a scrofulous suppurating gland; chronic abscess in connection with diseased bones; acute periostitis; aneurism; and malignant fungus.

A minute account is given of the best mode of extracting foreign bodies and hardened wax from the external meatus. Inflammation of this should never be neglected, apt as it is to pass on to the inner parts. When the lining membrane of the passage is the subject of chronic inflammation, the solution of nitrate of silver and the brown citrine ointment may be employed with much advantage, precisely as in the analogous ophthalmia tarsi; the general health being carefully attended to. *Hairs* may fall in upon the membrana tympani, and give much annoyance, till they are lifted out with forceps. Defective hearing, arising from contraction of the meatus, is one of the few diseases that may be relieved by the introduction of a small metallic tube, shaped like a wine funnel. Such instruments, however, "being silver gilt, and sold in very neat morocco cases", are often used when they are noways adapted to benefit.

Exostosis of the external meatus is not very rare: it seems usually connected in its origin with inflammatory action. Inflammation of the membrana tympani is one of

the commonest forms of otitis, and is indeed, as in the parallel cases of iritis, usually not an isolated affection, but accompanied by inflammation of the tympanic cavity and neighbouring parts. Then it may become dangerous not only to hearing, but to life itself, ending in caries of the mastoid process, if not of the petrous portion of the temporal bone. It is absolutely necessary that we should be familiar with the healthy aspect of this membrane, as viewed through the silver speculum in clear sunlight. How else can we pretend to trace aright the morbid changes which it undergoes—the vascularity, the opacity, the collapse of the membrane, appearances which Mr. Wilde's pages so well describe?

"In it will, according to my observation, be found characteristics of disease, and pathological changes from the normal structure, sufficient to account for at least two-thirds of the cases of impaired hearing, independent of mechanical impediments from wax, and the inflammations presenting otorrhoea which occur in practice."

Acute pain of the ear is *very rarely neuralgic*—an important caution to those who drop strong stimulants into the meatus; and the inflammation which it for the most part indicates is to be treated, as reason points out, by leeching the orifice of the meatus, poulticing, purging; in the later stages, blistering; and mercury is not to be withheld in cases of any severity, any more than we would withhold it in iritis. These are clear and sensible dogmata, and must, we think, command the assent of all judicious surgeons.

Subacute myringitis is unaccompanied by pain, but is equally destructive to hearing as the acute disease; the aspect of the membrane is much the same, and the treatment is based on the same principles. In this form of the disease, and also in *scrofulous* inflammation of the tympanic membrane, which usually occurs in the young, and is quite analogous to, may often alternate with, *scrofulous* ophthalmia, Mr. Wilde recommends the rational combination of local depletion and counterirritation with constitutional alteratives and tonics—a system which is found very useful in the ocular disease. Small doses of corrosive sublimate in tincture of bark he particularly recommends in the chronic form and stage. Myringitis is occasionally *syphilitic*, being usually a tertiary symptom, and to be treated like chronic syphilitic iritis; but, being painless, requires, of course, the speculum for detection. In one case, "on the morning on which salivation was produced, the hearing was restored almost miraculously".

The truth is, that in this, as in all other maladies, it is only by a judicious combination of local and constitutional treatment that a cure is to be sought for; and the practitioner who is versed in the great general principles of medical science, and who applies them carefully to the exigencies of the case in hand, will find much less mystery and difficulty in the matter than those who are always seeking after specifics, and sighing for definite "rules", according to which this or that malady is to be cured.

In *chronic* myringitis, as in chronic ophthalmia, moderate local depletion, and persevering counterirritation, with the cautious application of solution of the nitrate of silver by means of a hair pencil, will be the best local remedies; but thickening and lesions of the tympanic membrane will be as difficult to remove as albugines and leucomata usually are.

It is when permanent thickening and opacity of the membrane has occurred, that, in a few cases, we may try what can be done to improve the hearing by making an aperture in the diseased part: but as we know not what injury the parts within may have suffered from the previous disease, the result must be always doubtful. Mr. Wilde, like a good surgeon, discards all complicated screws and punches, and makes the opening with a sickle-shaped needle, touching it with nitrate of silver to keep it open.

Inflammation within the tympanum, or otitis proper, presents the same varieties, and in many respects the same symptoms as myringitis, because, in fact, the diseases are often combined. It may end in resolution, with some remaining deafness, or in suppuration; and consequent

bursting of the tympanic membrane; or, worst of all, in the disease passing to the bone, and ultimately to the brain. Palsy of the facial nerve is often produced, apparently by the extension of the inflammation to the canal in which it lies so near the tympanic cavity; and Mr. Wilde remarks that he has "not met with a single instance of Bell's paralysis unaccompanied by otorrhœa, caries, or cerebral affection, in which there were not manifest traces of disease, or its results, in the membrana tympani, or in the middle ear". This is well worthy of notice, as manifesting the propriety of the antiphlogistic treatment of these cases in the early stage.

The tympanic mucous membrane is likewise subject to catarrhal and chronic inflammation, exactly parallel to those of the conjunctiva; and which is to be treated on the principle above described.

Disease of the labyrinth must of necessity be equally obscure and dangerous. Mr. Wilde has in his possession a natural dissection of the osseous labyrinth, set free by caries, and pulled by Sir Philip Crampton out of the external meatus of one of his patients!

True nervous deafness, unconnected with local inflammatory lesions, is, in Mr. Wilde's opinion, much more rare than is supposed; and, when it does occur, is to be treated as one would do amaurosis, according to its cause, traced out as well as we can. No nostrum, no specific, and least of all the ether vapour douche through the Eustachian tube (which our author has fully and vainly tried), is to be trusted to; and though old and far gone cases are usually irremediable, in others a careful attention to the local, the cerebral, and the constitutional symptoms will often lead to great amendment.

Chapter viii is occupied with Otorrhœa, a symptom originating in various diseases of the ear, and occurring in 647 cases out of 2,385 at St. Mark's infirmary. Mr. Wilde gives a graphic though somewhat prolix description of the usual do-nothing mode of treatment in these cases, and enforces the necessity of prompt and appropriate management, since not only is otorrhœa a disgusting disease, but one never knows "how, when, or where it will end, or what it may lead to": caries of the temporal bone, and death from phlebitis and abscess of the brain, may be the sequence.

Thorough cleanliness, by frequent syringing, the removal of polypi (which occurred in no fewer than 64 out of 647 cases of otorrhœa), the careful touching of granulations on the membrane with nitrate of silver, the application of the solution of the same substance and of weak citrine ointment to the meatus, abstinence from plugging the ear with cotton, so that the membrane may be exposed to the free air, and the diligent use of counterirritation and constitutional treatment, are the means of cure.

Our space will not permit us to enter upon deaf-dumbness, the subject of Mr. Wilde's elaborate appendix; so here we conclude by once more strongly recommending this sterling work. Its occasional prolixity is its principal, and on a subject generally so little understood, its not unpardonable fault.

ON THE USE OF AN ARTIFICIAL MEMBRANA TYMPANI IN CASES OF DEAFNESS, DEPENDENT UPON PERFORATION OR DESTRUCTION OF THE NATURAL ORGAN. By JOSEPH TOYNBEE, F.R.S. pp. 47. London: 1853.

OF MR. TOYNBEE'S MERITS, let us hear Mr. Wilde speak:

"The labours and investigations of Mr. Toynbee have effected more for aural pathology than those of all his predecessors, either in England or on the Continent. He commenced at the right end, and has travelled in the proper direction. He has brought to bear upon the subject the true principles of science, and with the assistance of the microscope, the aid of every modern artistic appliance to assist him, accustomed to habits of minute dissection, patient research, and careful observation, he has accumulated a mass of facts upon the morbid anatomy of the organ of hearing that must lay the foundation for a more rational mode of treating the diseases of those parts than has heretofore been resorted to. Mr. Toynbee has laboured extensively, and with effect, to discover and describe the *post mortem*

appearances which disease has produced in the organ of hearing; and I trust he will long continue to prosecute, with the same avidity, the same honesty of purpose, and an equal amount of critical acumen, his valuable researches." (*Aural Surg.*, p. 37.)

We need not add to this praise from so good a judge, and can only express our satisfaction to see advertised by the author of the pamphlet we are now noticing, "a complete treatise on the Diagnosis and Treatment of Diseases of the Ear." Meantime, we have to deal only with the artificial membrana tympani, the subject of the present brochure.

While perforation of a thickened and inelastic membrane restores the patient, in some cases, to a considerable hearing power, replacement of a lost or perforated drum head has a similar good effect in others. This has been done, as our readers are aware, and with much success, by the application upon the perforation of a morsel of cotton wool moistened with oil; and Mr. Toynbee gives several cases in which a gutta percha membrane has been marvellously useful.

The first section of Mr. Toynbee's pamphlet describes the minute structure of the membrane, and the layers of which it consists; it is interesting anatomically at all events.

The second section treats of the functions of the membrane, of the tympanum, and of the Eustachian tube, in which he endeavours to show that the Eustachian tube is always closed, except during the act of swallowing, and that the tympanum is, therefore, practically a closed cavity. This conclusion we are not prepared to deny; yet we do not see how it logically follows from the well known fact that sonorous vibrations communicated to the petrous bone through the head are heard loudest when the external meatus is closed, that therefore those coming through the outer ear ought to be confined to the tympanic cavity for producing their full effect.

The third section consists of a description of the artificial membrane, with cases in which it has been used. It is made "by fixing the layer of gutta percha or vulcanised India rubber between two very delicate silver rings from the eighth to the sixth of an inch in diameter; these rings are riveted together, leaving a portion of the membrane drawn moderately tense in their centre; a margin of the membrane is also left beyond the circumference of the rings, so as to prevent the latter being in contact with and irritating the tube of the ear". To the surface of one of these rings the silver wire is fixed "of sufficient length to admit of the membrane being introduced or withdrawn by the patient."

Nine interesting cases follow, which, however, are too long to quote. They seem very satisfactory as to the improvement effected by the appliance, which is well worthy of more extensive trials.

An appendix on "Tonsil-cutting" follows, in which Mr. Toynbee agrees with Mr. Wilde that it is not useful, and may be very harmful. Many with tonsils enormously enlarged hear very acutely; and when deafness and swollen tonsils occur together, it is not that the glands close the Eustachian tube, but that there is a concomitant disease of the aural mucous membrane.

A FEW PRACTICAL OBSERVATIONS ON DEAFNESS AND DISEASES OF THE EAR, ARISING FROM SMALL POX, SCARLET FEVER, AND MEASLES. By P. ALLEN, M.D., F.L.S. pp. 70. London: 1853.

DR. ALLEN appears to have an extensive aural practice; and he has embodied some of the results of it in a paper written to be read before the Dorset Branch of the Association. For this, however, it turned out to be too voluminous, and he has therefore printed it in a separate form. His great objects are:—

I. "To point out the relation and connexion which exists between the tissue affected in variola, rubeola, and scarlatina, and the same structure in the organ of hearing."

In this, so far as we can judge, he has not succeeded.
II. "To describe the nature of the several diseases of the ear produced by these diseases."

III. "To consider the results of such several affections; their production of deafness, and the treatment to be adopted for its relief."

It is quite obvious that the author's plan includes a complete treatise on diseases of the ear, and perhaps also on the exanthemata. It is altogether so extensive that, to do it justice, a pamphlet of seventy pages is narrow, not voluminous; and we are not, therefore, surprised that the necessary compression of ideas in this work has occasionally produced confusion.

We are astonished that Dr. Allen should speak of "the meatus becoming dilated as widely as is necessary, or its sensibility will admit of" by the speculum: the meatus, being of cartilage and bone, may be straightened, but can hardly, we think, be dilated. Nor are we sure that a lamp "held between the teeth of the surgeon" is the best way of illuminating the passage.

Dr. Allen differs much from Mr. Wilde and Mr. Toynbee in his estimate of Eustachian catheterism: he values it much, and has performed it *four thousand times*, injecting warm air or water into the tympanum, or even making the catheter the medium of the electric current, which he says he has seen do good. We distrust the efficacy of the electric current: but the author's experience entitles his opinion to be received with respect.

REMARKS ON THE OPERATION OF BRONCHOTOMY. By WM. MARTIN, Esq., Bengal Medical Service. pp. 22. Calcutta: 1853.

We do not think that surgery would have lost much, had these "remarks" never been made.

The author draws, describes, and recommends a trocar wherewith to pierce the windpipe, as we understand, right through the skin, without any preparatory incision. He has tried the instrument but once; and that, be it observed, was in performing *laryngotomy* through the crico-thyroid membrane, an operation comparatively very easy, and where the parts are fixed and superficial, and where only a thorough blunderer could contrive to fail. *Tracheotomy* is the difficult thing; and we certainly should be very much disinclined to thrust a trocar in this heroic way through skin, and muscle, and tube: suppose the trachea eluded the point of the instrument, as it very likely might, where would the latter go? Besides, how did Mr. MARTIN succeed in his single trial of the easier operation?

"It did not, however, succeed entirely to our satisfaction; from deficient experience, I had not confidence that I might not carry the cutting part of the trocar, a full sized flat one, so far as to endanger the posterior surface of the larynx; and as time was pressing, I withdrew the instrument before the canula had perforated the crico-thyroid membrane, stopped the external bleeding, which was not profuse, and as quickly as possible, with a scalpel, opened the larynx at this point, carrying the incision downwards through the cricoid cartilage. In this way a sufficient opening was made, the operation having been somewhat simplified by the preliminary introduction of the trocar."

Is this encouraging?

RESEARCHES ON THE PRIMARY STAGES OF HISTOGENESIS AND HISTOLYSIS. By ROBERT D. LYONS, M.B. pp. 16. Dublin: 1853.

The object of this paper, reprinted from the proceedings of the Royal Irish Academy, is to trace the formation and the dissolution of organised structures, and the supposed parallel between the two.

As a general fact, there can be no question but that the body is composed of certain elements, to which it is again ultimately reduced; but we cannot say that we feel much enlightened in anything of a practical way by the elaborate investigation which this paper contains, or that it has rendered our ideas of these recondite processes much more clear.

The subject is a very difficult one, and must be followed out in the light of microscopic and chemical science with long patience towards a very doubtful result.

SANDGATE AS A RESIDENCE FOR INVALIDS. By GEORGE MOSELEY. 12mo. pp. 136. London: 1853.

SANDGATE is a pleasant village on the south coast of England, sixty-eight miles south-east of London and eight miles west of Dover. According to Mr. MOSELEY it forms one of the best marine residences for invalids, being well sheltered and possessed of numerous natural and artificial advantages.

"In its security from cold winds, it vies with any one place on the coast; and to those who have resided at Nice or Pau, and have felt the bitterness of the easterly winds of spring and winter at the former place, and the heavy rains and shifting weather of the latter, as well as the relaxing influence of its warm winds, I need not point out the difference between a *warm* and a *sheltered* situation." p. 7.

The information contained in Mr. Moseley's work is interesting and useful.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

FACIAL ANÆSTHESIA.

In the *Glasgow Medical Journal* for July, Dr. J. B. COWAN, of that city, has published a very complete article on the subject of facial anæsthesia. He draws his conclusions from the data furnished by published cases. We are, however, obliged to confine our abstract to the general results at which he has arrived.

By the term anæsthesia is meant loss of sensibility, or, as it is more fully defined in the work of Romberg, it implies "a diminution or loss of the energy of a sensory nerve, from its excitability or condensing power being reduced or destroyed."* Anæsthesia most commonly occurs, either as an immediate antecedent of motor palsy, or coincident with it; but it has been found to exist in various parts of the body, independent of any paralytic affection. When anæsthesia accompanies paraplegia, its extent seems to depend upon the producing cause. Thus, when paralysis is the result of spinal concussion, or of severe injury of the cord, along with the loss of motion, there is loss of sensation; while, in cases arising from disease or some spontaneous morbid alteration, sensibility is generally unimpaired. In cases either of complete or partial paralysis, the sensibility, without being destroyed, may be defective, and the anæsthesia may confine itself strictly to one seat.

Facial anæsthesia, or deficient or entire loss of sensibility in the parts supplied by the fifth pair of nerves, or in some of them, may result from disease of the cerebrum where the fifth nerve takes its origin, of the nerve within the cranium, or of the nerve after it has emerged from the cranium; and, according to the seat, Dr. Marshall Hall has shown that there is a striking contrast as far as regards one class of symptoms. Thus, where the disease is one of origin, there is insensibility of the eye and nostril; when it exists in the nerve exterior to the cranium, the eye is unaffected; while, should there be disorganisation or division of the nerve within the cranium, the eye is partially disorganised, owing to the destruction of its nutritive function. Romberg describes a peripheral and a centric anæsthesia of the fifth pair; the first distinguished by the isolated loss of conduction on the side of the lesion, while the physiological characteristic of the second lies in the crucial effect of the lesion. He shows how the precise seat of the disease may be diagnosed in the following propositions:—(a) "The more the anæsthesia is confined to single filaments of the trigeminus, the more peripheral the seat of the cause will be found to be. (b) If the loss of sensation affect a portion of the facial surface, together with the corresponding facial cavity, the disease may be assumed to involve the sensory fibres of the fifth pair, before they separate to be distributed to their respective destinations; in other words, a main division must be affected before or after its passage through the cranium. (c) When the entire sensory tract of the fifth nerve has lost its sensation, and there are at the same time derangements of the nutritive functions in the affected parts, the Casserian ganglion,

* Romberg on Diseases of the Nervous System. Syden. ed., vol. i, p. 192.

or the nerve in its immediate vicinity, is the seat of the disease. (d) If the anæsthesia of the fifth nerve is complicated with disturbed functions of adjoining cerebral nerves, it may be assumed that the cause is seated at the base of the brain." The disease may be a consequence of injury, may be spontaneous, or attributable to some exciting cause. It may be general or local, complete or incomplete; the first being when the whole of one side of the face, the second when only a portion is affected, and this latter is most likely to follow an injury, or to be an accompaniment of palsy of the motor branch of the fifth. The symptoms may develop themselves gradually, or may come on suddenly; and not unfrequently they are preceded by neuralgia. The most permanent symptom in many of the cases is absent altogether or less marked in others, owing to the difference in the seat of the lesion. The disease of the fifth nerve is frequently complicated with disease of other nerves, more particularly of the portio dura of the seventh.

The symptoms generally consist in complete or partial suspension of the functions of the trifacial nerve, loss of tactile sensibility in the parts supplied by it, viz. the integuments of the cheek and side of the head, the eyelids, conjunctiva, tongue, Schneiderian membrane, etc., accompanied by loss of taste on the side of the tongue which is affected, frequently by loss of smell and hearing, and by inflammation of the eye, terminating in ulceration of the cornea, and by no means uncommonly in total disorganisation of the globe. An addition to these symptoms is paralysis and wasting of the muscles of mastication. Although the parts may be destitute of sensibility, strictly speaking, the feeling of pain may be conveyed from the presence of some morbid process in the nerve. The nature of the affection often escapes notice for some time, the attention of the practitioner being directed to some one prominent symptom.

It does not appear that the disease is of more frequent occurrence at any particular period of life, but in young persons it is very uncommon in the permanent form. Partial loss of sensibility, however, may accompany a *blight* or temporary paralysis of the facial muscles.

Causes and Premonitory Symptoms. The occurrence of the disease is ascribed by the patients to a variety of causes; and there is a marked difference in the primary symptoms in different cases. Injuries, as pistol shots, have in several instances produced it. It is often sudden, and sometimes is only preceded by a slight perversion of sensibility, or by a tingling sensation. Frequently there are attacks of headache, or pains in the occipital region and in the side of the face, which is afterwards the seat of the anæsthesia. Dimness of vision may be a prominent symptom. In three or four cases it has occurred after a simple fit or an epileptic attack. Further, it happens as a consequent of facial paralysis; a fact which does not seem easily explicable in those instances where the motor power had been entirely recovered, before the sensory function had been destroyed.

(a) *The loss of common or tactile sensibility* is the main characteristic of the disease. In a complete case of facial anæsthesia, the whole of one side of the anterior part of the head, and of the face, with the exception of a small space (bounded by the zygoma, the course of the facial artery, and the lower margin of the jawbone), supplied by twigs from the cervical plexus, is destitute of sensation. The ocular and palpebral conjunctive, the side of the tongue, and the nostril corresponding with the affected part, as well as the gums, are insensible, but the pinna of the ear is unimplicated, although receiving twigs from the anterior auricular division of the inferior maxillary, and also the back part of the head. In the majority of cases, however, the anæsthesia is more limited, and in some is confined to a very small spot. The want of sensibility may exist along with very severe pain arising from inflammation, and the progress of disease in the nervous substance.

(b) *Ageusia.* Loss of taste is not invariably, though in a very large majority of cases, a concomitant of the loss of tactile sensibility on the side of the tongue, corresponding with the affected side of the face and head. The only modifications of this symptom are, that the taste may be perfect at the base of the tongue and lost in its anterior portion, and that the sense may be perverted but not destroyed. The presence of this symptom in cases of division or disease of the trifacial nerve has tended to elucidate the functions of that nerve, and has proved satisfactorily that the sense of taste resides in the lingual branch of the fifth and the glosso-pharyngeal. That the sense of taste in the anterior part is given by the branch of the fifth, is proved by the researches of Alcock and Reid, and still more so by its loss supervening on disease of that nerve. It has been argued, however, that this was dependent on defective nutrition; a supposition proved to be erroneous, in some cases at least, by the

suddenness with which it occurs, and with which it ceases. Where the whole of the tongue is alike destitute of sensation, which is the case in chronic disease of the fifth nerve, this may afford a plausible explanation. Romberg is inclined to the assumption, that the glosso-pharyngeal is the only nerve of taste. He strengthens his position by reference to cases in which, there being tactile insensibility of the facial integuments, the taste continued: or in which the taste was perfect, although the tongue was destitute of sensibility. Another argument he derives from the absence of imaginary taste in hyperæsthesia of the lingual nerve. But, in at least thirty of the published cases, the sense of taste in the fore part of the tongue was destroyed. Injury or division of the glosso-pharyngeal nerve impairs the sense of taste on the back of the tongue, and on the mucous membrane of the fauces; and, while the sense is destroyed in the fore part, in consequence of disease of the fifth, it commonly remains perfect in the back part. Recent researches go far to show that the sense of bitter taste is dependent on the glosso-pharyngeal, and that sweet, sour, and salt tastes, are proper to the lingual branches of the fifth.

(c) *Masticatory Movements.* The portio minor of the fifth pair, or motor division of the inferior maxillary nerve, sends branches to the muscles of mastication, the masseter, temporal, two pterygoid, anterior belly of digastric, and mylo-hyoid, supplying them with motory power. The buccinator, however, in facial anæsthesia, does not participate in the paralysis of motion; and hence the branch it receives from the fifth must be a purely sensory one, its motor powers being derived from the facial. Loss of motory power in the above muscles is a frequent accompaniment of facial anæsthesia; and, if the disease is of long standing, the muscles become loose and flaccid. That this system should not be of uniform occurrence admits of easy explanation. If the pathological condition be one involving all the roots, or if it implicate the inferior maxillary after it joins the portio minor, then there will exist paralysis of the muscles of mastication. If it exist in the ganglion, or in some of the other branches, the muscles will not be affected.

The centric anæsthesia of the fifth pair is described by Romberg as accompanying recent hæmorrhage in the brain. "It affects," he says, "the third branch of the fifth pair on the side opposite to that on which the lesion is seated." In the cases he had observed, there was always paralysis of the portio minor of the fifth, the patient being only able to masticate with the muscles of the opposite side of the face. He seems to be the only author who has met with and detailed cases of this kind.

It is evident that paralysis of the masticatory muscles is a valuable symptom, as diagnostic to a certain extent of the nature and seat of the morbid condition on which the anæsthesia depends.

(d) *Other Senses.* In addition to partial destruction or perversion of the sense of taste, the other senses are frequently either lost or impaired, where there is complete paralysis of the fifth nerve.

Sight. That the optic nerve is indispensable to vision is clear, while, at the same time, the fifth exercises a very remarkable influence over it, and in some animals it is its sole source. The conclusions of Alcock, in the *Cyclopædia of Anatomy and Physiology*, are, "that the optic nerve is the proper medium of perception to visual impressions, and that the co-operation of the fifth nerve is not even necessary, to enable the optic nerve to fulfil its function. As the instrument of the general sensibility of the structures of the eye, however, the fifth nerve may be the channel through which impressions not visual, though perhaps excited by an agent of vision, viz., light, may be conveyed." Dr. Mackenzie considers irritation of the fifth by no means an uncommon cause of *sympathetic amaurosis*.

Hearing. The power which the fifth nerve exercises over this sense is probably dependent on defective nutrition.

Smell. The loss or impairment of the sense of smell might naturally be looked for, in those cases of facial anæsthesia, where taste is destroyed, as there is an evident connexion between the two; although its precise nature may not be easily explained.

(e) *Nutritive Function of the Eyeball.* The next symptom of facial anæsthesia is defective nutrition of the eye, leading to inflammation, ulceration, and ultimately disorganisation of the eyeball; and this has been shown by Dr. Marshall Hall to occur chiefly when the disease attacks the nerve, before it has made its exit from the cranium. In a case of complete paralysis of the fifth, the conjunctiva is deprived of sensibility and is unaffected by chemical irritants. The cornea becomes opaque, inflammation of all the tunics of the eye follows, and ulceration of the cornea and destruction of the globe very rapidly ensue.

Writers differ as to whether these results are traceable to lesion of the fifth nerve as a primary cause, or to a combination of secondary causes; and it has been argued by Alcock and others, that the violence inflicted in the vicinity of the organ, its exposure through the deprivation of sensibility to the action of irritating matters, and the absence of the lachrymal secretion, are the conditions which tend to its inflammation and destruction. The balance of evidence appears to incline in favour of admitting the effects to ensue directly from a lesion of the nutritive filaments. Be this as it may, all the appearances mentioned above are found in facial *anæsthesia*, and form one of its most prominent symptoms.

(f) *General Motor Power of Face.* Reference has already been made to the destruction of motor power in the masticatory muscles; and it is unnecessary to allude to those cases in which, from conjunct disease of the facial nerve, there is paralysis of all the facial muscles. Occasionally, however, more limited destruction or impairment of mobility occurs.

The Treatment of facial anæsthesia can only be palliative, and directed to mitigate the symptoms. In some cases, decided benefit has been observed to follow the employment of local applications, such as blisters and leeches; and these, with cupping and purgatives, are the measures which may generally be had recourse to. Spontaneous cures are fortunately not unfrequent.

Morbid Appearances. The morbid conditions out of which facial *anæsthesia* springs differ from one another as to their precise nature and seat, but are rarely or never obscure. In some instances the nervous cords are the seats of lesion, and they may be found in three states, either hardened, softened, or atrophied. Tumours pressing on the nerve may disturb or destroy its functions. Finally, the disease may be of a more extensive character, situated in and involving a large portion of the cerebral mass. There are many other varieties in the nature and extent of the lesions, on which it is unnecessary to dwell.

EDITOR'S LETTER BOX.

CASE OF FENNEL versus ADAMS.

LETTER FROM C. F. J. LORD, ESQ., TO THE EDITOR.

SIR,—It is desirable that the strong feeling entertained by the profession in regard to the late trial, "*Fennell v. Adams*," should not pass away till we have defrayed the costs which Mr. Fennell has been driven to incur.

Those of your readers who have not a clear recollection of the case, will find in the leading articles of the *ASSOCIATION JOURNAL* (July 8th, 1853), *Medical Times and Gazette* (July 9th), and *Lancet* (July 23rd), comprehensive recitals, and just commentaries, very favourable to Mr. Fennell.

The Medico-Ethical Society of Manchester have given their powerful testimony to the legitimacy of the plaintiff's appealing to the profession, "on account of the great and undeserved injury that such charges of neglect of duty brought against him were calculated to produce"; and I am quite sure that the uprightness and benevolence of the profession will concur in this opinion. To subscribe and carry Mr. Fennell harmless from the pecuniary cost of the trial is, therefore, consistent with our professional character, due to our sense of brotherhood, and to our love of justice. Thus warm with the subject, I venture to call on my professional brethren, and to quote, on the spur of the moment, from the pretty little ballad written by a young lady, and sold in aid of the funds of the Medical Benevolent College:—

"It needs not great wealth a kind heart to display;
If the heart is but willing, it soon finds a way;
And the poorest one yet, in the humblest abode,
May help a poor brother a step on the road."

I am, etc.,

CHARLES F. J. LORD.

Hampstead, Sept. 11th, 1853.

[A subscription (limited to 10s. 6d.) has, we perceive by our advertising columns, been already commenced.—EDITOR.]

MEDICAL EDUCATION.

THE LICENSING BODIES OF ENGLAND.

The following bodies grant degrees, diplomas, and licenses to practise medicine and surgery in England:

UNIVERSITY OF OXFORD.

UNIVERSITY OF CAMBRIDGE.

UNIVERSITY OF LONDON.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE SOCIETY OF APOTHECARIES.

UNIVERSITY OF OXFORD.

Chancellor: The Earl of Derby. *High Steward:* The Earl of Devon. *Vice-Chancellor:* R. L. Cotton, D.D. *Registrar:* P. Bliss, D.C.L. *Professors:* Regius Professor of Medicine, J. Adey Ogle, M.D. Tomlins' Prælector of Anatomy, Ditto. Shearardian Professor of Botany, C. G. B. Daubeny, M.D. Lichfield's Clinical Medicine, J. Adey Ogle, M.D. Aldrichian Professor of Anatomy, Ditto. Aldrichian Professor of Medicine, Ditto. Aldrichian Professor of Chemistry, C. G. B. Daubeny, M.D. Lee's Lecturer in Anatomy, H. Wentworth Acland, M.D.

EXERCISES FOR DEGREES. I. To perform the Responses, consisting of an examination in the Greek and Latin languages, in the rudiments of Logic, or in Euclid's Elements of Geometry.

II. To be publicly examined in, 1st. The rudiments of religion; 2nd. The *literæ humaniores*; 3rd. The elements of the mathematical sciences, and of physics. In Medicine, all students (besides undergoing the two examinations for Bachelors of Arts) are examined in the Theory and Practice of Medicine, Anatomy, Physiology, and Pathology; in *Materia Medica*, and in Chemistry and Botany, so far as they illustrate the science of Medicine; and in two at least of the following writers: Hippocrates, Aretæus, Galen, and Celsus. For a Doctor's degree in Medicine, a dissertation is to be recited in the Schools. Degrees are conferred once a year.

UNIVERSITY OF CAMBRIDGE.

The degrees granted by this University are those of Bachelor of Physic, Doctor of Physic, and Licentiates *ad practicandum*.

A candidate for the degree of M.B. must have entered on his sixth year from the date of admission, have resided nine terms, and have passed the previous examination. The examination in Chemistry and Botany may take place at the end of three years from admission; that in Anatomy and Medicine at the end of four years. The exercises are one act and one opponyency.

The degree of M.D. is granted to a Bachelor of Physic of five years, or to a Master of Arts of seven years' standing. The exercises are two acts and one opponyency. The examinations and certificates are the same as for the license *ad practicandum*.

Candidates for a license *ad practicandum in medicind*, being previously M.B., must produce certificate of having attended hospital practice for three years, exclusive of the nine terms above mentioned, and of having attended lectures on Practice of Physic and Pathology, Anatomy and Physiology, Chemistry, Botany, Medical Jurisprudence, *Materia Medica* and Pharmacy, Principles of Surgery, Principles of Midwifery, and Practical Anatomy. If previously Masters of Arts, they must bring evidence of having been engaged in the study of Medicine five years after taking the degree of B.A., and of having attended hospital practice for three years.

UNIVERSITY OF LONDON (SOMERSET HOUSE).

Visitor: The Queen. *Chancellor:* The Earl of Burlington, LL.D. *Vice-Chancellor:* John G. Shaw Lefevre, Esq., C.B., F.R.S.; F.R.S. *Registrar:* R. W. Rotham, M.A., M.D. *Clerk to the Senate:* H. Moore.

EXAMINERS: FACULTY OF MEDICINE. Intellectual Philosophy, Logic, and Moral Philosophy: Rev. Henry Alford, B.D.; T. B. Burcham, Esq., M.A. Medicine: Archibald Billing, M.A., M.D., F.R.S.; Alexander Tweedie, M.D., F.R.S. Surgery: Sir Stephen L. Hammick, Bart.; Joseph Hodgson, Esq., F.R.S. Anatomy and Physiology: Francis Kiernan, Esq., F.R.S.; Wm. Sharpey, M.D., F.R.S. Physiology and Comparative Anatomy: W. B. Carpenter, M.D., F.R.S. Midwifery: Edward Rigby, M.D. Chemistry: W. Thomas Brande, Esq., F.R.S. Botany: Rev. J. S. Henslow, M.A. *Materia Medica* and Pharmacy: G. Owen Rees, M.D.

DEGREE OF BACHELOR OF MEDICINE. Candidates for the degree of Bachelor of Medicine are required—1. To have studied

during four years at one or more of the institutions recognised by this University. II. To have spent one year at least in one or more of the recognised institutions in the United Kingdom. III. To pass two examinations.

The FIRST EXAMINATION commences on the first Monday in August. The candidate must produce certificates—1. Of having completed his nineteenth year. 2. Of having taken a degree in Arts; or of having passed the matriculation examination. 3. Of having studied during two years at a recognised medical school, subsequently to having taken a degree in Arts, or passed the matriculation examination. 4. Of having attended lectures on each of four of the following subjects: Descriptive and Surgical Anatomy, General Anatomy and Physiology, Comparative Anatomy, Pathological Anatomy, Chemistry, Botany, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Midwifery and Diseases peculiar to Women and Infants, Surgery, Medicine. 5. Of having dissected during nine months. 6. Of having attended a course of Practical Chemistry. 7. Of having attended to Practical Pharmacy. The fee for examination is five pounds. Candidates are examined in Anatomy, Physiology, Chemistry, Botany, and Materia Medica and Pharmacy; they also translate passages from the Latin Pharmacopœia. In the week following, the examiners arrange in two divisions such candidates as have passed; and a certificate, signed by the registrar, is delivered to each candidate.

Any candidate who has been placed in the first division may be examined for honours, in the week following, in any or all of the following subjects:—Anatomy and Physiology, Chemistry, Materia Medica and Pharmaceutical Chemistry, and Structural and Physiological Botany. If sufficient merit be evinced, the highest candidates in Anatomy and Physiology, in Chemistry, and in Materia Medica and Pharmaceutical Chemistry, will each receive an exhibition of thirty pounds a year for two years; and the first and second candidates in each of these subjects and in Botany will each receive a gold medal of the value of five pounds. Certificates of honour are given.

The SECOND EXAMINATION commences on the first Monday in November. No candidate is admitted within two academic years of the first examination. Certificates required—1. Of having passed the first examination. 2. Of having subsequently attended lectures on each of two of the subjects in the foregoing list, for which the candidate did not present certificates at the first examination. 3. Of having, since the first examination, dissected during six months. 4. Of having conducted at least six labours. 5. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months, and lectures on clinical surgery. 6. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months, and lectures on clinical medicine. 7. Of having subsequently attended to practical medicine in a recognised hospital, infirmary, or dispensary, during six months. 8. Of moral character from a teacher in the last institution at which he studied. The fee for examination is five pounds. Candidates are examined in Physiology (including Comparative Anatomy); General Pathology, General Therapeutics, and Hygiene; Surgery; Medicine; Midwifery; Forensic Medicine: they are also required to translate passages of the Latin Pharmacopœia into English, and of the English Pharmacopœia into Latin, and to report on the cases of actual patients. In the following week, the examiners arrange in two divisions such candidates as have passed, and a certificate is delivered to each candidate.

Candidates placed in the first division may be examined for honours in any or all of the following subjects:—Physiology and Comparative Anatomy, Surgery, Medicine, Midwifery. In Physiology and Comparative Anatomy, in Surgery, and in Medicine, will the highest candidates each receive an exhibition of fifty pounds per annum for the next two years, with the style of University Medical Scholar; and the first and second candidates in these subjects, and the candidate who distinguishes himself most in Midwifery, each receives a gold medal of the value of five pounds. Certificates of honour are given.

DEGREE OF DOCTOR OF MEDICINE. The examination commences on the fourth Monday in November. Certificates required—1. Of having taken the degree of Bachelor of Medicine. 2. Of having attended, subsequently to having taken the above degree, (a) to Clinical or Practical Medicine during two years in a medical institution recognised by this university; (b) or, to Clinical or Practical Medicine during one year, and of having been engaged during three years in the practice of his profession; (c) or, if he have taken the degree of Bachelor of Medicine in this university, of having been engaged during five years in the practice of his profession. (One year of attendance on

Clinical or Practical Medicine, or two years of practice, will be dispensed with in the case of those candidates who at the second examination were placed in the first division.) 3. Of moral character, signed by two persons of respectability. The fee for examination is ten pounds.

Candidates are examined in—Elements of Logic and Moral Philosophy, Medicine, Surgery, and Midwifery. A thesis is written on a subject in Medicine, Surgery, or Midwifery, at the option of the candidate.

SPECIAL REGULATIONS. Certain parts of the above regulations are remitted in the case of candidates who commenced their medical studies in or before January 1839, or who were admitted by one of the licensing bodies prior to 1840.

ROYAL COLLEGE OF PHYSICIANS, LONDON (PALM-MALL EAST, TRAFALGAR SQUARE).

President: Dr. John Ayrton Paris. Censors: Drs. Nairne, Barker, Owen Rees, and Seth Thompson. Elects: Dr. Thomas Turner, Clement Hue, John Bright, Edward Thomas Monro, Thomas Mayo, Henry Herbert Southey, Francis Hawkins. Treasurer: Dr. Edward Thomas Monro. Registrar: Dr. Francis Hawkins.

The Examiners for the License are the President and Censors. The examinations take place at or about Christmas, Easter, Midsummer, and Michaelmas. The Examiners for the Extra-License are the President and three Elects. The examinations for the License and the Extra-License take place at the same time.

FEES. License, £56:17, including £15 stamp. Fellowship, £55:1, including £25 stamp. Extra License, about £25.

Every candidate for a license or extra license must produce evidence; 1. Of unimpeached moral character. 2. Of having completed the twenty-sixth year of his age. 3. Of having devoted himself for five years at least to the study of medicine.

The course of study ordered by the College comprises:—Anatomy and Physiology; the Theory and Practice of Physic; Forensic Medicine; Materia Medica and Botany; and the Principles of Midwifery and Surgery; attendance for three entire years on the physicians' practice of some general hospital or hospitals in Great Britain or Ireland, containing at least 100 beds. Candidates who have been engaged in practice and are forty years of age, may be admitted to examination upon presenting such testimonials of character, general and professional, as shall be satisfactory.

The first examination is in anatomy and physiology; the second in the causes and symptoms of diseases; the third in the treatment of diseases. The examinations are carried on usually during three days by writing, and two days *visd voce*.

The candidate is called on to translate *visd voce* into Latin a passage from Hippocrates, Galen, or Aretæus; or to construe into English a portion of the works of Celsus, or Sydenham, or some other Latin medical author.

The fellows are elected from the body of licentiates—a certain number generally on the 25th of June.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (LINCOLN'S INN FIELDS).

President: James Luke. Vice-Presidents: G. J. Guthrie and W. Lawrence. The Council: The President and Vice-Presidents; R. Keate; T. Copeland; Sir B. C. Brodie, Bart.; B. Travers; C. Hawkins; J. Swan; J. H. Green; E. Stanley; J. M. Arnott; J. F. South; F. C. Skey; J. Hodgson; T. Wormald; G. Pilcher; J. Bishop; G. W. Mackmurdo; F. Kiernan; W. Coulson; G. Gulliver; and R. Partridge. Court of Examiners. The President and Vice-Presidents; B. Travers; E. Stanley; J. H. Green; J. M. Arnott; John F. South. Examiners for the Fellowship in Classics, Mathematics, and French: G. Smith; G. G. Stokes; and I. Brasseur. Professor of Anatomy and Physiology: F. C. Skey. Hunterian Professor and Conservator of Museum: R. Owen. Conservator: J. T. Quekett. Librarian: T. M. Stone. Secretary: E. Belfour. Clerk: H. P. Gregg. Mace-bearer: W. Stone.

CANDIDATES FOR THE DIPLOMA OF MEMBER OF THE COLLEGE are required to produce the following certificates, viz:—1. Of being twenty-one years of age. 2. Of having been engaged during four years in the acquirement of professional knowledge. 3. Of having studied practical pharmacy during one year. 4. Of having attended at a recognised hospital or hospitals in the United Kingdom the practice of physic during one year, and one summer session. The winter session commences on the 1st of October, and terminates on the 31st of March. The summer session commences on the 1st of June, and terminates on the 31st of September. The course of study comprises a period of three months, and

mences on the 1st of May, and terminates on the 31st of July. No provincial hospital will be recognised by this College which contains less than 100 patients; and no metropolitan hospital which contains less than 150 patients. 5. Of having attended, during three winter and two summer sessions, the practice of surgery at a recognised hospital or hospitals in the United Kingdom. 6. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during three winter sessions. 7. Of having attended, during two winter sessions, lectures on the principles and practice of surgery. 8. Of having attended, during one summer session, lectures on materia medica, and lectures on midwifery; practical midwifery to be attended at any time after the conclusion of the session. 9. And of having attended one course of lectures on the practice of physic, and one course on chemistry.

The course of study hereby prescribed is required to be observed by candidates who shall have pursued their studies in hospitals and schools in England.

Certificates will not be received from candidates who have studied in London, unless they shall have registered their tickets at the College, as required by the regulations, during the last ten days of January, March, and October in each year; nor from candidates who have studied elsewhere, unless their names duly appear in the registers of their respective schools.

In the certificates of attendance on hospital practice and on lectures, it is required that the dates of commencement and termination be clearly expressed.

Blank forms of the certificates may be obtained on application to the secretary, to whom they must be delivered, properly filled up, ten days before the candidate can be admitted to examination.

The regulations respecting the education of candidates for the Certificate of Qualification in Midwifery, and for the Fellowship, may be obtained on application to the Secretary.

THE SOCIETY OF APOTHECARIES.

Master: J. Parrott, Esq. *Wardens:* C. Griffith, Esq.; and R. N. B. Ward, Esq. *The Court of Examiners:* E. Tegar, Esq., *Chairman:* H. Combe; A. M. Randall; Richard Hopkins Robertson; Richard King; Robert Norton; Thomas Peregrine; R. C. Walsh; R. Druiitt; R. H. Semple; W. G. T. Dyer; and S. H. Ward, Esqs. *Secretary to the Court of Examiners:* Henry Blatch, Esq. *Clerk to the Society:* Robert Brotherson Upton, Esq. *Professor of Botany:* John Lindley, Esq., Ph.D., F.R.S., G.S., etc. *Professor of Chemistry and Materia Medica:* Wm. Thos. Brande, Esq., F.R.S. *Examiner for the Society's Prizes in Materia Medica and Therapeutics:* J. Copland, M.D., F.R.S. *Examiner for the Society's Prizes in Botany:* N. B. Ward, Esq., F.R.S., F.L.S. *Curator of the Botanic Garden:* Mr. T. Moore. *Beadle:* Mr. C. Rivers.

REGULATIONS TO BE OBSERVED BY STUDENTS INTENDING TO QUALIFY THEMSELVES TO PRACTISE AS APOTHECARIES IN ENGLAND AND WALES. (DATED 1848.) Candidates must produce testimonials: 1. Of having served an apprenticeship of not less than five years to a legally qualified apothecary; or of an apprenticeship for not less than five years to surgeons practising as apothecaries in Ireland and Scotland. 2. Of having attained the age of twenty-one years: as evidence of age, a copy of the baptismal register will be required in every case where it can possibly be obtained. 3. Of good moral conduct. 4. Of having pursued a course of medical study in conformity with the regulations.

COURSE OF STUDY. Every candidate whose attendance on lectures shall have commenced on or after the 1st of October, 1849, must attend the following lectures and medical practice during not less than three winter and two summer sessions; each winter session to consist of not less than six months, and to commence not sooner than the 1st, nor later than the 15th of October; and each summer session to extend from the 1st of May to the 31st of July.

FIRST YEAR. *Winter Session:* Chemistry; Anatomy and Physiology; Anatomical Demonstrations. *Summer Session:* Materia Medica and Therapeutics; Botany and Vegetable Physiology; Midwifery and Diseases of Women and Children.

SECOND YEAR. *Winter Session:* Anatomy and Physiology; Anatomical Demonstrations; Dissections; Principles and Practice of Medicine; Medical Practice. *Summer Session:* Medical Practice; Midwifery and Diseases of Women and Children; Forensic Medicine; Practical Chemistry; Morbid Anatomy; Clinical Medicine.

THIRD YEAR. *Winter Session:* Dissections; Principles and Practice of Medicine; Medical Practice; Morbid Anatomy; and Clinical Medicine.

Practical Midwifery at any time after the conclusion of the first course of midwifery lectures.

The above course of study may be extended over a longer period than three winter and two summer sessions, provided the lectures and medical practice are attended in the order prescribed.

Medical Practice must be attended during the full term of eighteen months: twelve months at a recognised hospital, and six months either at a recognised hospital or dispensary.

In place of the Second Course of Lectures on the Theory and Practice of Medicine, the Court will admit a certificate of attendance on a course of Clinical Lectures, delivered in a recognised hospital by a distinct professor, consisting of not less than seventy-five lectures, attended by the student after the first systematic course upon the Theory and Practice of Medicine.

Those gentlemen whose attendance on lectures commenced before the 1st of October, 1849, will be allowed to complete their studies in conformity with the previous regulations of the court.

The certificates of teachers recognised by the medical authorities in Dublin, Edinburgh, Glasgow, and Aberdeen, and of medical professors in foreign universities, are received.

No hospital will be recognised unless it contain at least 100 beds, and it be under the care of two or more physicians, who give a regular course of clinical lectures and instruction in morbid anatomy; also, unless the apothecary be legally qualified. No dispensary will be recognised unless situated in some town where there is a recognised medical school, and be under the care of at least two physicians and an apothecary legally qualified. No medical practice will be available unless it be attended in conformity with the course of study prescribed.

REGISTRATION OF TESTIMONIALS. All testimonials must be given on a printed schedule, with which students will be supplied at the end of their first registration: In London, at the Hall. In the provincial towns, from the gentlemen who keep the registers of the medical schools.

All students, in London, are required *personally* to register the several classes for which they have taken tickets. Tickets of admission to lectures and medical practice must be registered in October and May; but no ticket will be registered unless it be dated within *seven* days of the commencement of the course.

The court requires students at the provincial medical schools to register their names in their own handwriting, with the register of each respective school, within the first twenty-one days of October, and first fourteen days of May; and to register their certificates of having duly attended lectures on medical practice within fourteen days of the completion of such attendance.

PRELIMINARY EXAMINATION IN CLASSICS AND MATHEMATICS. Three times in each year, in November, March, and July, an examination takes place in classics and mathematics for articleed students who have not yet entered to their second winter session of their curriculum; and students who pass this examination are not again examined in Latin, except in the Pharmacopœia Londinensis and Prescriptions. The subjects of examination, and the dates, will be announced in the medical journals at least three months before each examination.

PRELIMINARY LATIN EXAMINATION. On the first Saturday in the months of December, January, February, April, May, June, and October, those students who have completed two winter sessions of their medical studies may be admitted to an examination in Celsus and Gregory, provided there be twenty names on the list. Candidates must enter their names in a book kept at the beadle's office, on or before the preceding Monday, and attend at half-past three o'clock p.m., on the day of examination.

Those gentlemen who fail to pass this examination satisfactorily will not be readmitted until they appear for their general examination.

GENERAL EXAMINATION. Every person intending to offer himself for examination must give notice in writing to the clerk of the society, on or before the Monday previously to the day of examination, and must deposit all the required testimonials at the office of the beadle.

The examination of the candidate for a certificate of a qualification to practise as an apothecary will be as follows:

In translating portions of the first four books of Celsus de Medicinâ, and of the first twenty-three chapters of Gregory's Conspectus Medicinæ Theoreticæ; in Physicians' Prescriptions, and the Pharmacopœia Londinensis; in Chemistry; in Practical Chemistry; in Materia Medica and Therapeutics; in Botany; in Anatomy; in Physiology; in the Principles and Practice of Medicine, including Midwifery and the Diseases of Children.

The court meet in the Hall every Thursday, where candidates are required to attend at a quarter before four o'clock.

Sums to be paid for certificates: For London, and within ten miles thereof, ten guineas: for all other parts of England and Wales, six guineas. Persons having paid the latter sum become entitled to practise in London, and within ten miles thereof, by paying four guineas in addition.

For information, students are referred to the beadle, at Apothecaries' Hall, every day (Sunday excepted), between ten and four o'clock.

HOSPITALS AND MEDICAL SCHOOLS IN ENGLAND.

The following is a list of the hospitals and medical schools in England.

IN LONDON.

ST. BARTHOLOMEW'S HOSPITAL (Smithfield).
CHARING CROSS HOSPITAL (West Strand).
ST. GEORGE'S HOSPITAL (Hyde Park Corner).
GUY'S HOSPITAL (Southwark).
KING'S COLLEGE HOSPITAL (Portugal Street, Lincoln's Inn).
KING'S COLLEGE MEDICAL SCHOOL (Somerset House).
LONDON HOSPITAL (Whitechapel).
ST. MART'S HOSPITAL (Paddington).
MIDDLESEX HOSPITAL (Charles Street, Berners Street).
ROYAL FREE HOSPITAL (Gray's Inn Road).
ST. THOMAS'S HOSPITAL (Southwark).
UNIVERSITY COLLEGE (Upper Gower Street).
WESTMINSTER HOSPITAL (Westminster Abbey).
SCHOOL OF ANATOMY AND MEDICINE ADJOINING ST. GEORGE'S HOSPITAL (1, Grosvenor Place).

IN THE PROVINCES.

BIRMINGHAM.—QUEEN'S COLLEGE.
—SYDENHAM COLLEGE.
BRISTOL.—MEDICAL SCHOOL.
HULL.—SCHOOL OF MEDICINE AND ANATOMY.
LEEDS.—SCHOOL OF MEDICINE.
LIVERPOOL.—ROYAL INFIRMARY SCHOOL OF MEDICINE.
MANCHESTER.—ROYAL SCHOOL OF MEDICINE AND SURGERY.
—CHATHAM STREET SCHOOL OF MEDICINE.
NEWCASTLE-UPON-TYNE.—COLLEGE OF MEDICINE AND PRACTICAL SCIENCE.
—COLLEGE OF MEDICINE IN CONNECTION WITH THE UNIVERSITY OF DURHAM.
SHEFFIELD.—MEDICAL INSTITUTION.
YORK.—MEDICAL AND SURGICAL SCHOOL.

ST. BARTHOLOMEW'S HOSPITAL.

PHYSICIANS: Dr. Hue, Dr. Roupell, and Dr. Burrows. SURGEONS: Mr. Lawrence, Mr. Stanley, and Mr. Lloyd. ASSISTANT PHYSICIANS: Dr. F. J. Farre, Dr. Jeaffreson, and Dr. Black. ASSISTANT SURGEONS: Mr. Skey, Mr. Wormald, and Mr. Paget. PHYSICIAN ACCOUCHEUR: Dr. West.

FEES. *Medical Practice*. Six months, £10:10; nine months, £12:12; eighteen months, £15:15; unlimited, £31:10.

Surgical Practice. Six months, £15:15; twelve months, £21; three years, £26:5; unlimited, £31:10.

The hospital contains 650 beds; of which 420 are devoted to surgical cases, and 230 to medical cases and diseases of women. The clinical clerks are elected from among the most diligent students. The fees for dresserships are: three months, £12:12; six months, £18:18; twelve months, £26:5.

MEDICAL SCHOOL. WINTER SESSION. Medicine. Dr. G. Burrows; M., W., and F., at half-past 3 P.M. One session, £5:5; perpetual, £7:7.

Surgery. Mr. Lawrence; M., W., and Th., at 7 P.M. Fees, £5:5, and £7:7.

Descriptive and Surgical Anatomy. Mr. Skey; daily, except Saturday, at half-past 2 P.M. Half session, £5:5; whole session, £7:7; unlimited, £10:10.

Anatomy and Physiology. Mr. Paget; daily, at 9 A.M. Half session, £5:5; whole session, £7:7; unlimited, £10:10. Dissecting rooms open daily from 7 A.M. to 4 P.M.

Practical Anatomy. Mr. Holden and Mr. Coote demonstrate daily from half-past 10 to half-past 2.

Chemistry. Mr. Stenhouse; M., W., and F., at 10 A.M. Fees, £5:5, and £8:8.

SUMMER SESSION. *Materia Medica and Therapeutics*. Dr.

Roupell; M., W., Th., and F., at half-past 2 P.M. Fees, £5:5, and £7:7.

Botany. Dr. F. J. Farre; Tu., Th., and Sat., at 9 A.M. Fees, £3:3, and £4:4.

Forensic Medicine. Dr. Baly; M., W., and F., at 9 A.M. Fees, £3:3, and £4:4.

Midwifery and Diseases of Women and Children. Dr. West; daily, except Sat., at half-past 3. Fees, £4:4, and £6:6.

Comparative Anatomy. Mr. McWhinnie; M., W., and F., at 10. Fees, £2:2, and £3:3.

Practical Chemistry. Mr. Stenhouse; M., Tu., Th., and F., from 10 till 1. Fees, £2:2, and £3:3.

Natural Philosophy. Dr. Gibbon; W. and Sat., at 12. Fee, £2:2.

Entrance fee to all lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries, £52:10; lectures and hospital practice for same, £94:10; unlimited entrance to all lectures, £62. The fees may be paid in two or in three portions at the commencement of the first winter and summer sessions.

SCHOLARSHIPS AND PRIZES. Examinations of the classes are held at the close of each session; and various scholarships and prizes are awarded.

CHARING CROSS HOSPITAL.

CONSULTING PHYSICIAN: Dr. Shearman. PHYSICIANS: Dr. Golding and Dr. Chowne. ASSISTANT-PHYSICIAN: Dr. Rowland. SURGEONS: Mr. Hancock and Mr. Avery.

FEES. *Medical Practice*. Six months, £10:10; full period required, £15:15.

Surgical Practice. Six months, £10:10; full period required, £15:15.

Full period to both medical and surgical practice, £26:5.

MEDICAL SCHOOL. WINTER SESSION. Medicine. Dr. Chowne and Dr. Rowland; M., W., and F. Fees, £4:4, and £7:7.

Surgery. Mr. Hancock; M., Th., and F. Fees, £3:3, and £5:5.

Descriptive and Surgical Anatomy. Mr. Canton; daily, except Sat. Fees, £4:4, and £7:7.

Anatomy and Physiology. Mr. Canton; daily, except Sat. Fees, £4:4, and £7:7.

Anatomical Demonstrations. Mr. Goldsbro; daily. Fees, £2:2, and £4:4.

Chemistry. Mr. Lewis; Tu., Th., and Sat. Fees, £5:5, and £7:7.

SUMMER SESSION. *Materia Medica and Therapeutics*. Dr. Steggall and Dr. Willshire; daily, except M. Fees, £4:4, and £6:6.

Botany. Mr. F. W. Headland; daily. Fees, £3:3, and £4:4.

Forensic Medicine. Dr. Birkett and Mr. Hird; M., W., and F. Fees, £2:2, and £4:4.

Midwifery, and Diseases of Women and Children. Dr. Chowne and Mr. Hird; M., Tu., Th., and F. Fees, £3:3, and £6:6.

Practical Chemistry. Mr. Lewis; Tu., Th., and Sat. Fee, £2:2.

General fee for all the lectures required by the College of Surgeons and Society of Apothecaries, exclusive of Practical Chemistry, £45.

Various prizes and testimonials of honour are awarded.

ST. GEORGE'S HOSPITAL.

PHYSICIANS: Dr. J. A. Wilson, Dr. Nairne, Dr. Page, and Dr. Benée Jones. ASSISTANT PHYSICIANS: Dr. Pitman and Dr. Fuller. OBSTETRIC PHYSICIAN: Dr. R. Lee. SURGEONS: Mr. Cæsar Hawkins, Mr. Cutler, Mr. Tatum, and Mr. H. C. Johnson. ASSISTANT SURGEONS: Mr. P. Hewett and Mr. G. D. Pollock.

FEES. *Medical Practice*. Six months, £8:8; twelve months, or the period required by the Hall, £16:16; unlimited, £25:4; fee to the apothecary, £1:1.

Surgical Practice. Six months, £15:15; twelve months, or the period required by the College, £21; unlimited, £26:10.

The hospital contains 350 beds.

Instruction in practical pharmacy—six months, £12:12; one year, £15:15. The pupils attending medical and surgical practice may become, when qualified, clinical clerks. The dresser of the surgeon of the week boards at the hospital free of expense. Perpetual pupils are eligible to be assistant house-surgeons for six months, and house-surgeons for twelve months (without additional fee), when properly qualified.

MEDICAL AND SURGICAL SCHOOL. *Materia Medica and Therapeutics*. Dr. Nairne and Dr. Page; M., W., and F. Fees, £5:5, and £6:6.

* Where two sums are mentioned, the first denotes the fee for one course; the second that for unlimited attendance.

Surgery. Mr. Tatum; M., W., and F., at 12. Fees, £4:4, and £6:6.

Descriptive and Surgical Anatomy. Mr. P. Hewett and Mr. Pollock; daily, except Sat., at a quarter before 3. Fees, £6:6, and £8:8.

Anatomy and Physiology. Mr. Athol Johnson; M., Tu., Th., and F., at 10 A.M. Fees, £8:6, and £8:8.

Practical Anatomy. Students will be directed in their studies during several hours daily, by Mr. Henry Gray, Dr. Ogle, and Mr. T. Holmes, under the superintendence of the lecturers.

Chemistry. Mr. H. M. Noad; Tu., Th., and Sat., at 11 A.M. Fees, £6:6, and £8:8.

SUMMER SESSION. Materia Medica. Dr. Pitman; daily, except Sat., at 11 A.M. Fees, £5:5, and £6:6.

Botany. Mr. Henfrey; daily, except Sat., at 10 A.M. Fees, £3:3, and £4:4.

Medical Jurisprudence. Dr. Fuller; M., W., Th., and F., at 12. Fees, £3:3, and £4:4.

Midwifery. Dr. R. Lee; daily, at 9 A.M. Fees, £4:4, and £6:6.

Practical Chemistry (including use of materials). Mr. Noad; daily, at half-past 2. Fee for course, £4:4.

The whole of the lectures and hospital practice required by the College of Surgeons of England and Society of Apothecaries of London may be attended on payment of £42 at the commencement of the first year; £42 at the commencement of the second year; and £12:12 at the commencement of the third year. The payment for the year will admit the pupil to all the lectures, and to the hospital practice required, for that year only. Registration fee, one guinea.

SCHOLARSHIPS AND PRIZES. The examinations of those students who are candidates for prizes and certificates of merit will take place at the end of each course. Various scholarships and prizes are also awarded.

OUTY'S HOSPITAL.

Sent too late for insertion this week.

KING'S COLLEGE.

Prospectus not forwarded.

LONDON HOSPITAL.

PHYSICIANS: Dr. Cobb, Dr. Little, and Dr. Fraser. **SURGEONS:** Mr. Luke, Mr. Adams, and Mr. Curling. **ASSISTANT PHYSICIANS:** Dr. Davies, Dr. Parker, and Mr. Gibbon. **ASSISTANT SURGEONS:** Mr. Critchett, Mr. N. Ward, and Mr. Wordsworth.

General fee for attendance on the medical and surgical practice, qualifying for the examinations at the London University, Royal College of Surgeons, and Apothecaries' Hall, and for perpetual attendance on all the lectures, £88:4, payable in two instalments of £44:2 each, at the commencement of the two first sessions. Perpetual fee to the lectures alone, £50. Students can make special entries for lectures or practice.

WINTER SESSION. Medicine. Dr. Little: Mon., Wed., Th., and Sat. Fees, £4:4, and £7:7.

Surgery. Mr. Curling and Mr. Critchett: Mon., Wed., and Fr. Fees, £4:4, and £6:6.

Descriptive and Surgical Anatomy. Mr. Adams: daily (except Thursday). Fees, £5:5, and £10:10.

General Anatomy and Physiology. Dr. Carpenter: Tu. and Th. Fees, £3:3, and £5:5.

Practical Anatomy. Mr. N. Ward and Mr. Wordsworth: daily. Demonstrations on Tu., Th., and Sat. Fees, £5:5, and £10:10.

Chemistry. Dr. Letheby: Mon., Wed., Fr., and Sat. Fees, £4:4, and £7:7.

SUMMER SESSION. Materia Medica and Therapeutics. Dr. H. Davies: Mon., Wed., Th., and Sat. Fees, £3:3, and £4:4.

Botany. Mr. Bentley: M., W., and F. Fees, £3:3, and £4:4.

Forensic Medicine. Dr. Ramsbotham and Dr. Letheby: daily (except Saturday). Fees, £3:3, and £4:4.

Midwifery and Diseases of Women and Children. Dr. Ramsbotham. Fees, £4:4, and £6:6.

Practical Chemistry. Dr. Letheby: Tu., Th., and Sat. Fees for students of the hospital, £2:2; other persons, £3:3.

The anatomical museum and reading room are open daily.

ST. MARY'S HOSPITAL.

PHYSICIANS: Dr. Alderson, Dr. Chambers, and Dr. Sibson. **SURGEONS:** Mr. Coulson, Mr. Lane, and Mr. Ure. **PHYSICIAN-ACCOCHEUR:** Dr. Tyler Smith. **SURGEON-ACCOCHEUR:** Mr. I. Baker Brown. **OPHTHALMIC SURGEON:** Mr. White Cooper. **AURAL SURGEON:** Mr. Toynbee. **ASSISTANT PHYSICIANS:** Dr. Handfield Jones, Dr. Sieveking, and Dr. Markham. **ASSISTANT SURGEONS:** Mr. Smith, Mr. Haynes Walton, and Mr. James

Lane. DENTAL SURGEON: Mr. Nasmyth. **RESIDENT MEDICAL OFFICERS:** Mr. Trotter, Mr. Bullock, and Mr. Lawrence.

This hospital contains 150 beds, 85 of which are devoted to surgical, and 65 to medical cases. These include a ward of 10 beds for diseases of women, two small wards for ophthalmic cases, and beds for aural cases.

FEES. Medical Practice. Three months, £5:5; six months, £7:7; twelve months, £12:12; eighteen months, £15:15; perpetual, £21.

Surgical Practice. Six months, £9:9; twelve months, £21; three years, £21; perpetual, £32:10.

There are three resident medical officers, who board in the hospital, and are appointed for eighteen months, two non-resident medical officers, a curator, and a medical and a surgical registrar, who are appointed by the weekly board on the recommendation of the medical committee; these offices are open to competition among the pupils of the hospital. Clinical clerks and dressers will also be selected from the best qualified students without extra fee.

MIDDLESEX HOSPITAL.

PHYSICIANS: Dr. Francis Hawkins, Dr. Crawford, and Dr. Seth Thompson. **PHYSICIAN-ACCOCHEUR:** Dr. Frere. **ASSISTANT PHYSICIANS:** Dr. Stewart and Dr. Goodfellow. **SURGEONS:** Mr. Shaw, Mr. De Morgan, and Mr. Moore. **ASSISTANT SURGEON:** Mr. Henry. **SURGEON-DENTIST:** Mr. Tomes. **APOTHECARY:** Mr. Corfe. **REGISTRAR:** Mr. Sibley.

FEES. Medical Practice. Three months, £6:6; six months, £10:10; eighteen months, £15:15; unlimited, £21.

Surgical Practice. Six months, £10:10; twelve months, £12:12; three years, £18:18; unlimited, £21; fee to apothecary, £1:1; fee to secretary, 6s.

Students desirous of entering to the medical and surgical practice, apart from the lectures, for the periods required by the College of Surgeons and Apothecaries' Company, may do so by making one payment of £30. The hospital receives 300 in-patients, and contains wards appropriated to the admission of cases of syphilis, of cancer, and of uterine disease. Clinical clerks and dressers are selected from the most deserving pupils without additional fee. Pupils become eligible as dressers to the in-door patients, after having practised dressing and bandaging in the out-patient room and surgery. House-surgeons are elected half-yearly from the dressers, fee £21; and are provided with board and residence in the hospital.

CLINICAL PRIZES. The physicians and surgeons have instituted two prizes, of the value of ten guineas each, which will be awarded, at the annual distribution, to the students who shall present the best reports of cases in the hospital during the preceding winter session.

TREASURERS' PRIZE. An annual prize, value ten guineas, is offered by the treasurers.

MEDICAL AND SURGICAL SCHOOL. WINTER SESSION. Medicine. Dr. Crawford and Dr. Seth Thompson; M., W., and F., at 9 A.M. Fees, £4, and £6.

Surgery. Mr. Shaw; Tu., Th., and Sat., at 9 A.M. Fees, £4, and £6; two courses, £5:5.

Descriptive and Surgical Anatomy. Mr. Moore; daily, at 12. Fees, £8, and £11.

Physiology and General Anatomy. Mr. De Morgan; M., W., and F., at 3 P.M. Fees, £4, and £6.

Practical Anatomy. Mr. T. W. Nunn and Dr. Van der Byl; demonstrations, Tu. and Th., at 3 P.M. Fees, £2:2, and £3:3.

The dissecting room is open from eight to five o'clock daily.

Single Course of Anatomy, Physiology, Demonstrations, and Dissections, £8:8; perpetual, £15.

Morbid Anatomy. Mr. Henry; M., at 10 A.M. Fees, £2:2, and £3:3.

Chemistry. Mr. Thomas Taylor and Mr. Heisch; M., W., and F., at 11 A.M. Fees, £8, and £8.

Practical Pharmacy, with Dispensing. Mr. Corfe. Fee for six months, £8:8; for twelve months, £12:12; without dispensing, for three months, £6:6.

SUMMER SESSION. Materia Medica, etc. Dr. Stewart; daily, except Sat., at 3 P.M. Fees, £3:3, and £5:5.

Botany. Mr. Bentley; daily, except F., at 11 A.M. Fees, £3, and £4.

Medical Jurisprudence. Dr. Goodfellow; daily, except M., at 9 A.M. Fees, £3:3, and £5:5.

Midwifery. Dr. Frere; daily, except M., at 10 A.M. Fees, £3, and £5.

Comparative Anatomy. Mr. G. R. Waterhouse; Tu. and F., at 5 A.M. Open to all general pupils of the school. Fee from occasional students, £2:2.

Practical Chemistry. Mr. T. Taylor and Mr. C. Heisch; M. W., and F., at 11 A.M. Fee for general pupils, £2:2; non-general pupils, £3:3.

Clinical Lectures on M., W., Th., and F., at 1 P.M.

Practical Histology and the Use of the Microscope. Dr. Van der Byl; twice a week. Fee, £2:2.

Attendance on all the hospital practice and lectures required by the College and Hall, exclusive of practical chemistry, £75; which may be paid by instalments of £30 at the beginning of the first session; £30 at the beginning of the second session; and £15 at the beginning of the third session. Fee for every additional session, £5. Admission to the Library and Reading Room is included in the fees paid by general students. Occasional students, who desire to make use of the Library, may do so on payment of 10s. 6d. The Museum is open daily to students, and bones and models are supplied to them for study during the intervals of lecture.

ROYAL FREE HOSPITAL.

PHYSICIANS: Dr. Brinton and Dr. Arthur Hassall. SURGEONS: Mr. W. Marsden, Mr. J. Gay, and Mr. T. Wakley. ASSISTANT-SURGEON: Mr. Weedon Cooke. MEDICAL OFFICER FOR DISEASES OF CHILDREN (Out-patients): Mr. T. Carr Jackson. DENTIST: Mr. Robinson. CUPPER: Mr. Atkinson. HOUSE-SURGEONS: Mr. G. F. Lane and Mr. J. B. Curgiven. APOTHECARY: Mr. Morgan. SECRETARY: Mr. W. H. Fenn.

The Royal Free Hospital contains 160 beds. They are classed in equal proportions for medical and surgical cases. A Maternity Department is attached to the hospital, under the superintendence of the physician-accoucheurs.

The Museums of anatomy, materia medica, and the herbarium, are open daily to the students of the respective classes, from 10 to 3 o'clock.

MEDICAL AND SURGICAL SCHOOL. WINTER SESSION. Principles and Practice of Medicine. Dr. A. Hassall and Dr. E. Ballard; M., Tu., Th., and Sat., at 4 P.M. Fees, £4:4, and £6:6.

Surgery. Mr. Thomas Wakley and Mr. Victor de Méric; M., W., and F., at 8 P.M. Fees, £4:4, and £6:6.

Descriptive and Surgical Anatomy. Dr. R. Knox; daily, at half-past nine. Fees, £5:5, and £8:8.

Anatomy and Physiology. Mr. F. J. Gant; daily, at 11 P.M. Fees, £4:4, and £6:6.

Chemistry. Dr. R. M. Glover; M., W., Th., and F., at 12 P.M. Fees, £4:4, and £6:6.

At the conclusion of the course, a few lectures will be delivered by Dr. Hassall on the Chemistry and Pathology of the Urine, and the Treatment of Renal Diseases.

SUMMER SESSION. Materia Medica and Therapeutics. Dr. E. Ballard; daily, at 3 P.M. One session, £3:3.

Botany. Mr. J. F. Syme; M., Tu., W., and F., at half-past 9. One session, £3:3.

Forensic Medicine. Dr. J. R. Cormack; M., Tu., and Th., at 11 A.M. One session, £3:3.

Midwifery, and Diseases of Women and Children. Dr. Tyler Smith, Dr. Robert Barnes, and Dr. Henry Bennet; M., W., and F., at 4 P.M. One session, £4:4.

Practical Chemistry. Dr. R. M. Glover.

FEES FOR HOSPITAL PRACTICE. Medical: Twelve months, £10:10; perpetual, £15:15. Surgical: Twelve months, £10:10; perpetual, £15:15. Fee perpetual for medical and surgical practice, £26:5.

General fee for all the lectures and hospital practice required by the College of Surgeons and the Society of Apothecaries, £65.

The fees for "perpetual" attendance at any of the lectures may be paid by two equal instalments in October and January.

The offices of house-surgeon, clinical clerks, and dressers, will be conferred on the students without fees of any kind; competency, as tested by an examination, being the only qualification that will be required.

At the termination of the winter and summer sessions, examinations will be instituted. Honorary certificates will be awarded to those students who may distinguish themselves. Clinical honorary certificates will also be granted to those students who, at the end of the year, may produce the best reports of cases treated in the hospital.

ST. THOMAS'S HOSPITAL.

CONSULTING PHYSICIAN: Dr. Roots. CONSULTING SURGEON: Mr. Green. PHYSICIANS: Dr. Barker, Dr. Risdon Bennett, and Dr. Golden. ASSISTANT PHYSICIANS: Dr. Cohen and Dr. Peacock. SURGEONS: Mr. South, Mr. Mackmurdo, Mr. Solly, Mr. Le Gros Clark, and Mr. Simon. OBSTETRIC PHYSICIANS:

Dr. Waller and Dr. Griffith. OPHTHALMIC SURGEON: Mr. Mackmurdo.

Admission fee to hospital practice and all the lectures, £40 for the first year, a similar sum for the second, and £10 for each succeeding year, or £90 at one payment for an unlimited attendance.

Gentlemen proposing to become students of St. Thomas's Hospital are expected to produce satisfactory testimonials of moral character and general education.

Examinations are held at Christmas, and at the end of the winter and summer terms.

WINTER COURSE. Theory and Practice of Medicine. Dr. Bennett; M., W., and F., at 4 P.M.

Clinical Medicine. Dr. Barker; M. and W., at 3 P.M.

Surgery. Mr. South; Tu., Th., and Sat., at 11 A.M.

Ophthalmic Surgery. Mr. Mackmurdo; Tu., Th., and F., at 9 A.M.

Descriptive and Surgical Anatomy. Mr. Clark; Tu., Th., F., and Sat., at 3 P.M.

Physiology and General Anatomy. Mr. Grainger; M., Tu., W., and Th., at 10 A.M.

Microscopical Anatomy. Mr. Grainger and Mr. Rainey; F., at 10 A.M.

Anatomical Demonstrations. Mr. Rainey, Mr. Barwell, and Mr. Jones; daily, from 9 to 3.

Chemistry. Dr. R. Dundas Thomson; M., W., and F., at 4 P.M.

General Pathology. Mr. Simon; Course of Twelve Lectures (during January), Tu., Th., and Sat., at 4 P.M.

The Teeth, their Structure and Diseases. Mr. E. Saunders, at 10 A.M. (during the course of Physiology).

Clinical Lectures in Midwifery. Dr. Waller and Dr. Griffith.

SUMMER COURSE. Materia Medica. Dr. Peacock; M., Tu., W., and F., at 8 A.M.

Botany. Dr. Bristowe; Tu., Th., and Sat., at 10 A.M.

Forensic Medicine. Dr. Brinton; Tu., Th., and Sat., at 8 A.M.

Midwifery. Dr. Waller; M., W., Th., and F., at 9 A.M.

Comparative Anatomy and Natural History. Dr. E. Meryon; Tu. and Sat., at 9 A.M.

Practical Chemistry. Dr. R. D. Thomson; M., W., and F., at 11 A.M.

Clinical Medicine. Dr. Barker; M. and Th., at 3 P.M.

SCHOLARSHIPS, PRIZES, ETC. A scholarship of £20 is awarded to the student who shall be first in a voluntary classical and mathematical examination at the commencement of his studies at the hospital.

SUBJECTS. Classics: Greek—Homer, 1st Book of Iliad; New Testament, Gospel of St. Matthew. Latin: Virgil, 1st and 2nd Books of Georgics, Cicero, 2nd Philippic. Mathematics: Arithmetic, Algebra, up to and including Quadratic Equations; Euclid, 1st Three Books.

Various other scholarships and prizes are given. Two house-surgeons, and a resident accoucheur, provided with rooms and commons free of expense. The house-surgeons are selected annually from the dressers who have obtained their diplomas to practise; and the resident-accoucheurs from the students, on examination. Fifteen dressers are selected every six months, and provided with rooms and commons in the hospital, free of expense, during their attendance.

UNIVERSITY COLLEGE.

Prospectus not forwarded.

WESTMINSTER HOSPITAL.

Prospectus not forwarded.

SCHOOL OF MEDICINE ADJOINING ST. GEORGE'S HOSPITAL.

Prospectus not forwarded.

QUEEN'S COLLEGE, BIRMINGHAM.

WINTER SESSION. Medicine. Dr. Johnstone. Fees, £4:4, and £7:7.

Surgery. Mr. Sands Cox. Fees, £3:3, and £6:6.

Descriptive and Surgical Anatomy. Mr. J. Cox.

Anatomy and Physiology. Mr. Parker. Fees, £6:6, and £10:10.

Practical Anatomy. Mr. Bolton and Mr. O. Pemberton. Fees, £3:3, and £5:5.

Chemistry. Mr. Shaw. Fees, £6:6, and £9:9.

SUMMER SESSION. Materia Medica and Therapeutics. Heslop and Mr. Knowles. Fees, £4:4, and £5:5.

Botany. Mr. Knowles. Fees, £3:3, and £5:5.

Forensic Medicine. Dr. J. B. Davies. Fees, £3:3, and £5:5.

Midwifery and Diseases of Women and Children. Mr. Berry. Fees, £3:3, and £6:0.

Practical Chemistry. Mr. Shaw.

The course of study required by the College of Surgeons and the Society of Apothecaries, may be attended on the payment of a composition fee of £42, exclusive of college fees, £5 per annum, and of hospital practice, £21. The payment may be made at once, or in two equal sums,—at matriculation, and twelve months afterwards.

SYDENHAM COLLEGE (12, ST. PAUL'S SQUARE, BIRMINGHAM).

Principal: Bell Fletcher, M.D. *Treasurer:* James Russell, M.D. *Honorary Secretaries:* Messrs. Alfred Baker and Alfred Hill.

WINTER SESSION. Medicine. Dr. Fletcher. Fees, £4:4, £7:7.

Surgery. Mr. A. Baker. Fees, £4:4, and £7:7.

Descriptive and Surgical Anatomy. Mr. Elkington, Mr. Jones, and Mr. Postgate. Fees, £4:4, and £7:7.

Anatomy and Physiology. Dr. Keyworth. Fees, £4:4, and £9:9.

Anatomical Demonstration. Mr. Jones and Mr. Postgate.

Chemistry. Mr. A. Hill. Fees, £4:4, and £7:7.

SUMMER SESSION. *Materia Medica.* Dr. Russell and Mr. Bassett. Fees, £4:4, and £7:7.

Midwifery. Dr. Elkington. Fees, £3:3, and £4:4.

Forensic Medicine. Mr. Orford. Fees, £3:3, and £4:4.

Botany. Mr. Westcott. Fees, £3:3, and £4:4.

Composition fee for all the lectures required by the College and Hall, £42; matriculation fee, £1:1; reading room and museum fee (annually), £1:1; porter's fee for each class, 2s. 6d.

BRISTOL MEDICAL SCHOOL.

WINTER SESSION. Medicine. Dr. Budd and Dr. Stanton; M., T., W., and F. Fees, £4:4, and £6:0.

Surgery. Mr. Clark and Mr. Prichard; M., W., and F. Fees, £4:4, and £6:0.

Descriptive and Surgical Anatomy. Mr. Prichard and Dr. Brittan; daily. Fees, £5:5, and £9:9.

General Anatomy and Physiology. Dr. Brittan and Mr. Coe; daily. Fees, £5:5, and £8:8.

SUMMER SESSION. *Materia Medica* and Therapeutics. Dr. Stanton; daily. Fees, £4:4, and £6:0.

Botany. Mr. Rootsey. Vegetable Physiology. Dr. Brittan; daily. Fees, £3:3, and £5:5.

Midwifery. Dr. J. G. Swayne; daily. Fees, £4:4, and £6:6.

Forensic Medicine. Dr. Kay.

Toxicology. Mr. Herapath; daily. Fees, £3:3, and £5:5.

Practical Chemistry. Mr. Herapath. Fee, £3:3.

Fee for perpetual attendance on all the above courses, exclusive of Practical Chemistry, £47:5.

The Bristol Royal Infirmary contains 242 beds. FEES. Surgeon's Pupil (non assistant): first year, £20; second year, £12:10; third year, £7:10; three years at one payment, £35.

Surgeon's pupil (dresser): first year, £35; second year, £30; third year, £25; three years at one payment, £80.

Physician's pupil, £15 per annum.

St. Peter's Hospital contains 228 beds, including wards for lying-in and venereal patients, an asylum for pauper lunatics.

Pupils are also received at the Bristol General Hospital and at the Bristol Dispensary. The Medical Practice of the General Hospital is recognised on the same terms as that of a Dispensary. Fee for eighteen months £15.

HULL SCHOOL OF MEDICINE AND ANATOMY.

Prospectus not forwarded.

LEEDS SCHOOL OF MEDICINE.

WINTER SESSION. Principles and Practice of Physic. Dr. Chadwick and Dr. Heaton; daily, except Saturday. Fees, £5:5, and £3:3.*

Principles and Practice of Surgery. Mr. Hey and Mr. Nunneley; Tu., Th., and Sat. Fee, £3:3.

Descriptive Anatomy. Mr. W. M. Price and Mr. C. G. Wheelhouse; M., Tu., Th., and F. Fees, £4:4, and £3:3.

Anatomy, Physiology, and Pathology. Mr. Ikin, Mr. S. Hey, Mr. Price, and Mr. Wheelhouse; five days in the week. Fees, £6:0, and £4:4.

Chemistry. Mr. Morley and Mr. Scattergood; daily, except Sat. Fees, £4:4, and £3:3.

SUMMER SESSION. *Materia Medica* and Therapeutics. *Dr. Clarke; daily. Fees, £5:5, and £3:3.

Botany. Dr. Heaton; M., Tu., Th., and F. Fees, £2:12:6, and £1:11:6.

Forensic Medicine. Dr. Pyemont Smith; M., Tu., Th., and F. Fees, £2:12:6, and £1:11:6.

Midwifery and Diseases of Women and Children. Mr. Smith and Mr. Braithwaite; daily. Fees, £3:3, and £2:2.

Practical Chemistry. By Mr. Scattergood.

Operative Surgery.

Fee for perpetual admission to all the courses, £42.

Application for tickets may be made to the treasurer, Mr. S. Hey, Albion Place.

Clinical lectures will be given at the General Infirmary, on medical cases, by Dr. Chadwick and Dr. Heaton; on surgical cases, by Mr. Smith, Mr. T. P. Teale, and Mr. Samuel Hey; on ophthalmic and aural practice, at the Eye and Ear Infirmary, by Mr. Nunneley.

LIVERPOOL INFIRMARY SCHOOL OF MEDICINE.

FEES. *Medical and Surgical Practice.* First year, £18:18; second year, £12:12; third year, 10:10; three years, £36:15.

WINTER SESSION. Medicine. Dr. Dickinson: Mon., Wed., Th., and Fr. Fee, £5:5.

Surgery. Mr. Cooper: M., W., Th., and F. Fee, £4:4.

Anatomical Demonstrations and Dissections. Mr. F. D. Fletcher; daily (except Saturday). Fee, £3:3.

Anatomy, Physiology, and Pathology. Mr. Long: daily. Fee, £5:5.

Chemistry. Dr. Brett: Tu., Th., and Sat. Fee, £5:5.

Clinical Medicine. Dr. Vose and Dr. Turnbull: Wednesday.

Clinical Surgery. Mr. Cooper: Tuesday.

SUMMER SESSION. *Materia Medica* and Therapeutics. Dr. Inman: daily. Fee, £4:4.

Botany. Dr. Nevins: daily. Fee, £3:3.

Medical Jurisprudence. Dr. Brett and Mr. Fletcher: four days weekly. Fee, £3:3.

Midwifery, and Diseases of Women and Children. Mr. Batty: daily. Fee, £3:3.

Practical Chemistry. Dr. Brett: three days weekly. Fee, £3:3.

Ophthalmic Medicine and Surgery. Dr. R. Hibbert Taylor: Tu. and Fr. Fee, £1:1.

Clinical Medicine. Dr. Dickinson: Friday.

Clinical Surgery. Mr. Cooper: Tuesday.

Fees to all the lectures required by the Hall and College, including Practical Chemistry, £45, payable in advance.

MANCHESTER ROYAL SCHOOL OF MEDICINE AND SURGERY (PINE STREET).

WINTER SESSION. Medicine. Dr. Browne; daily, except Sat. Fee, £4:4.

Surgery. Mr. Orr; M., W., and F. Fee, £4:4.

Descriptive and Surgical Anatomy. Dr. Renaud; daily. Fee, £4:4.

Anatomy and Physiology. Mr. Turner and Mr. Smith; daily.

Anatomical Demonstrations. Mr. Lund; daily. Fee, £2:2.

Chemistry. Dr. Allan; daily, except Sat. Fee, £4:4.

SUMMER SESSION. *Materia Medica* and Therapeutics. Mr. Childs. Fee, £4:4.

Botany. Mr. Grindon. Fee, £3:3.

Forensic Medicine. Mr. Greaves. Fee, £3:3.

Midwifery and Diseases of Women and Children. Mr. Heath. Fee, £4:4.

Practical Pathology. Dr. Renaud. Fee, £2:2.

Microscopical Anatomy. Mr. Smith.

Ophthalmic Surgery. Mr. Hunt and Mr. Lund. Fee, £1:1.

Practical Chemistry. Dr. Allan. Fee, £3:3.

Perpetual Practice to all the lectures required by the examining bodies, £42.

CHATHAM STREET SCHOOL OF MEDICINE, MANCHESTER.

WINTER SESSION. Medicine. Dr. Watts and Dr. Wilkinson. Fees, £4:4, and £6:0.

Surgery. Mr. Southam. Fees, £4:4, and £6:0.

Descriptive and Surgical Anatomy. Mr. J. S. Fletcher and Mr. J. O. Fletcher. Fees, £4:4, and £6:0.

Anatomy and Physiology. Mr. Dumville. Fees, £4:4, and £6:0.

Anatomical Demonstrations. Mr. Murphy.

Chemistry. Mr. Stone. Fees, £5:5, and £7:7.

SUMMER SESSION. *Materia Medica* and Therapeutics. Mr. Somers. Fees, £3:3, and £5:5.

Botany. Dr. Jepson. Fee, £3:3.

Forensic Medicine. Dr. Aikenhead. Fee, £3:3.

Midwifery and Diseases of Women and Children. Dr. Whitehead and Dr. Schöpf-Merei. Fees, £3:3, and £5:5.

* In this school, the second named fee is for the second session; and entitles the pupil to perpetual attendance on the class.

Practical Pathology. Dr. Watts.
 Microscopical Anatomy. Dr. Jepson.
 Ophthalmic Surgery. Dr. A. Todd.
 Perpetual fee for attendance on all the lectures, £42.
 Hospital practice at the Royal Infirmary.
 Several prizes and scholarships are awarded.
 Further particulars may be obtained from the Registrar, Mr. Southan, Salford, Manchester, or from any of the Lecturers.

NEWCASTLE UPON-TYNE COLLEGE OF MEDICINE AND PRACTICAL SCIENCE.

SHEFFIELD MEDICAL INSTITUTION.

Prospectus not forwarded.

YORK SCHOOL OF MEDICINE.

PHYSICIANS TO THE HOSPITAL: Dr. Belcombe, Dr. Simpson.
 SURGEONS: Mr. Russell, Mr. Hey. PHYSICIANS OF THE DISPENSARY: Dr. Simpson, Dr. Laycock, Dr. Shann. SURGEONS: Mr. Dodsworth, Mr. W. Matterson, Mr. Moore, Mr. Keyworth.
 FEES. *Medical Practice*. Eighteen months, £12:12; perpetual, £15:15.

Surgical Practice. One year, £12:12; perpetual, £15:15. Perpetual to both medical and surgical practice, £26:5.

Pupils entering to the surgical practice will be allowed to dress the patients in their turn without additional fee.

WINTER SESSION. *Medicine*. Dr. Laycock; daily except Sat. Fees, £5:5, and £8:8.

Surgery. Mr. Russell and Mr. Keyworth; M., W., and F. Fees, £3:3, and £5:5.

Descriptive and Surgical Anatomy. Mr. Hornby and Mr. North; M., W., F., and Sat. Fees, £4:4, and £7:7.

Anatomy and Physiology. Mr. Edward Allen and Mr. Hornby; daily. Fees, £0:6, and £10:10.

Chemistry. Mr. Procter; daily, except Sat. Fees, £5:5, and £7:7.

SUMMER SESSION. *Materia Medica and Therapeutics*. Mr. Williams; daily. Fees, £5:5, and £7:7.

Botany. Mr. Moore; daily. Fees, £2:12:6, and £4:4.

Forensic Medicine. Mr. Procter; four days in a week. Fees, £2:12:6, and £4:4.

Midwifery. Mr. J. Allen and Mr. Anderson; daily. Fees, £3:3, and £5:5.

Perpetual admission to all the above courses, £42.

ADVERTISEMENTS.

Medical Books.—Thomas Jones, MEDICAL BOOKSELLER, 91, ALDERSGATE STREET, has always on hand a large Stock of Books, of Ancient and Modern Authors; also the most favourite Class Books of the present time; and he continues to allow his usual liberal discount on New Publications.—His Second-hand Stock will be found, at prices, worthy of inspection.

On October 1 will be published, Part II, 8vo, sewed, completing
Valentin's Text-Book of Physiology.

Translated by DR. BRINTON.

"The best Text-book of Physiology ever published."—*Dab. Med. Quart.*
 "An excellent translation of this admirable work, in which completeness and brevity appear to have been the author's object."—*Lancet.*
 "We cordially recommend the work."—*Brit. and For. Medical.*

London: HENRY RENSHAW, 356, Strand.

On the 1st of October will be published, in 8vo,
The Pathology and Treatment of PULMONARY TUBERCULOSIS. By JOHN H. BENNETT, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh. SUTHERLAND & KNOX, Edinburgh. SIMPKIN, MARSHALL & Co., London.

Immediately, in 2 vols., with Portrait, 4to.

Memoirs of John Abernethy, F.R.S.; with a View of his WRITINGS, LECTURES and CHARACTER. By GEORGE MACILWAIN, F.R.C.S., Author of "Medicine and Surgery One Inductive Science", etc.

A Treatise on Cataract, and the Operation for its Removal by Absorption with the Fine Needle through the Cornea. By ARTHUR JACOB, M.D., F.R.C.S., Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, by the same Author, 12mo, price 6s.

The Inflammations of the Eyeball: being

a TREATISE on all the Species and Varieties of IRITIS. London: JOHN CHURCHILL, Princes Street, Soho.

COURT OF QUEEN'S BENCH, WESTMINSTER, BEFORE A SPECIAL JURY.

FENNEL v. ADAMS.

"Defamation flies like the wind, while refutation halts lazily behind: the world receives the one with avidity, while it looks with suspicion on the other."—*Capt. Marryat.*

Mr. Fennell has been exposed need-

lessly and wantonly, not to say wickedly, to the anxiety and risk of clearing his character from unjust aspersions: this has been hard enough. By his appeal to a Court of Law, he has further incurred large pecuniary costs: this is harder still. As by the expensive trial he has done good service to the whole body of General Practitioners: should these fail to recognise his position, and withhold their sympathy, this would be the hardest part of all. Sanction has been given to the cause by the Medical Press; vide *Association Journal*, July 8; *Medical Times*, July 9; *Lancet*, July 23. Also by the Medical Society of Manchester.

The following gentlemen will form a Committee to watch over and receive subscriptions, an extension of which they earnestly solicit, that they may defray speedily Mr. Fennell's heavy costs in the late action.

Any money received beyond Mr. Fennell's expenses through the trial will be given in equal portions to the funds of the Medical Benevolent College and the Medical Benevolent Fund.

Subscriptions to be limited to 10s. 6d.

Dr. COLLET Worthing.

Mr. CORDY BURNHAMS Brighton.

Mr. PROPERT New Cavendish Street, London.

Mr. LORD Finchley Road, Hampstead.

Mr. SUDLOW ROOTS Kingston.

N.B. Subscriptions will be received by the above gentlemen, or at the Office of the Association Journal, 37, Great Queen Street, Lincoln's Inn Fields; or through Post Office Order on Hampstead Post Office, payable to CHARLES LORD, who will act as Treasurer.

MEDICAL BENEVOLENT COLLEGE.

Notice is hereby given, That, after

the 29th instant, the OFFICES of the COLLEGE will be at No. 37, SOHO SQUARE, where every information relative to the Institution may be obtained of the Secretary, either personally or by letter.

By Order of the Council,

EDWARD HENRY SIEVEKING, M.D.,

Hon. Sec.

4, HANOVER SQUARE,
 21st Sept. 1863.

HERBERT WILLIAMS, Assist. Sec.

Caution.—Shameless Imitation of

M. BOURJEAUD'S ELASTIC APPARATUS.—M. Bourjeaud, whose spiral method of compression is giving such general satisfaction to the Profession and the Public, as applied to Elastic Stockings, Abdominal Belts, Suspensory Bandages for Hydrocele, Varicocele, etc., and to the new Hernia Belt and Air Pad, is compelled, by the most flagrant imitations of his Apparatuses, to caution the Medical Profession against their clumsy and worse than useless copies of his original inventions. M. Bourjeaud begs the favour of a direct communication from such professional gentlemen who would escape the deceptions of these bare-faced imitators, they having gone so far as to rob him of all they could appropriate, even to his very words and engravings.

11, DAVIES STREET, BERKELEY SQUARE (opposite Mirvat's Hotel).
 At Home from One until Five o'Clock p.m.

To the Professional Judgment we

submit the Patent RESILIENT BODICE and CORSALETTI DI MEDICI. The basis principle is the arrangement of elastic materials in the back and sides, each portion having a distinct and separate action in conformity with muscular movement and anatomical structure, the oblique transverse resilient being variable in number, size, and position, as individual configuration may require. The quilted silk or fine flannel under the open transverse work conduces to warmth of the spine, and favours free exhalation from the skin.—PATENTED IN ENGLAND, FRANCE, and AUSTRIA. Enlarged Prospectus, with illustrations and prices, on receipt of two stamps for postage.

MARION and MAITLAND, 64, Connaught-terrace, Hyde-park, London.

RUPTURES.—BY ROYAL LETTERS PATENT.

The Moc-Main Lever Truss is allow-

ed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided; a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer, Mr. WHITE, 223, Piccadilly, London.

Elastic Stockings for Va-

RICOSE VEINS, and all cases of Weakness and Swelling of the Legs, Sprains, etc. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price from 7s. 6d. to 15s.

MANUFACTORY—223, PICCADILLY, LONDON.

THE PROFESSION AND THE CHOLERA.

AGAIN, and at our doors, has the tocsin of pestilence been sounded. The cry to the battle-field, where death wars against life with more giant energy than on the plains of Waterloo, is borne on the air; and to us as a profession comes the call for manful energy, and a hand to hand death-encounter. Regrets that the time of immunity from disease has been suffered to roll on without energetic action, and with no preparation for its advent, are now all in vain; and the responsibility of inaction must be indeed heavily felt by those august bodies whose pre-eminent duty it should be, as it appears to us, to conserve the public health; in all times of emergency, to give advice and assistance; and when this time has passed, by the advocacy of sound measures of sanitary reform to prevent its recurrence. It cannot cease to be matter of regret that, with the abundant materials placed at their disposal, the London College of Physicians has allowed another epidemic of cholera to invade this country without placing before the profession the lesson taught by the last.

What public authorities have failed to accomplish, it remains for us as individuals energetically, at this crisis, to perform. In silence, unnoticed, and after seeing the praises we have deserved borne away by others who have talked while ours have been the burden and heat of the day, it is still our duty—and we feel proud in knowing how well the duty will be done, in the midst of discouragement, and surrounded by scenes of appalling misery and destitution—to go onward to alleviate, by the kindness of our art and the consolations of our presence, the visitation of pestilence in the haunts of dirt, of famine, and of disease.

But as yet there is time for a note of warning ere the dread visitation is fairly domiciled amongst us; and it behoves us to do all in our power to arouse the lethargic, to enrol the willing, to organize and direct, and, by all means in our power, to afford another to the accumulated evidences that we are, as a profession, of all bodies the most unselfish and humane.

In all towns where there is no Sanitary Committee or Board of Health, the medical men should meet, and publish, with the sanction of the authorities, some such precautionary notice as the following, to be posted in all courts, alleys, and back streets. We select the following

merely as a specimen of the sort of notice which is required. Of course the words may be variously modified, according to circumstances; but the leading points to be impressed on the public are indicated in the subjoined placard.

“PREVENTATIVES AGAINST CHOLERA. Let every kitchen, cellar, and all underground premises, be thoroughly cleansed and whitewashed: and see that no gutter is choked, or any filth, ashes, or stagnant water, is allowed to accumulate in or near any of your premises. Give notice to the inspector at once of any nuisance that you know of anywhere near your house: and help your neighbours thoroughly to cleanse and purify the streets or courts in which you live.

“Cholera does not come on at once; there is first, perhaps for some days, looseness of the bowels, or purging, *without any pain*. But no one must be put off their guard by this, but get an order to the infirmary, or to the union surgeon, or procure some other medical advice, immediately. This will prevent diarrhoea from becoming cholera. Cholera is often brought on by improper food. Sour or unripe fruits and vegetables, especially uncooked, should be avoided.

“All excess must be carefully guarded against. *Dirt and drink* always bring on cholera, and drunkards always suffer most. Be moderate in eating and drinking; avoid exposure to the cold and wet, especially to foggy night air. If your clothes get wet, change them immediately.

“By attention to these simple rules, you will avoid cholera, both in your houses and in the town.

“By order of the Sanitary Committee,

“W. H. MICHAEL, *Chairman*.”

“Swansea, Sept. 21st, 1853.”

The medical men should confer with the authorities of the town or district in which they reside, and help and direct them as to the best modes of thoroughly cleansing all courts and alleys, and removing filth and nuisances of every description. They should originate a fund for the relief of destitution and distress; and organize a thorough system of house to house visitation, immediately upon the appearance of cholera, or even the ordinary autumnal diarrhoea. The medical men of a town or district should confer together, and determine such arrangements as would make the labour and toil be equally divided; while, at the same time, boards of guardians, or a public meeting of the inhabitant rate-payers, might pass such resolutions as would secure to the medical attendants a proper and fixed remuneration, say 10s. 6d., for each case of cholera or severe diarrhoea. At the same time, the poor should be informed as to where medicines and appliances could be procured at a moment's notice, and where medical advice might be at once obtained. This might be well accomplished by a central dispensary, where one, two, or three assistants, according to the number of cases, might be kept constantly at work, and where one or more might devote his time to a tabular record of cases, their results, treatment, etc.; for we feel assured that it is at the moment while the disease is rife that facts should be collected, to be reasoned on at leisure.

The isolation of the destitute and dirty from their

wretched and filthy habitations cannot be too much insisted on; and the fitting up a large airy warehouse as a temporary cholera hospital would become a necessary step in our precautions; while another might, with equal, if not greater service, be used as a refuge for the families attacked. Indeed, we believe, upon the whole, after the most careful consideration and considerable experience, that, instead of removing the patient, it is often better to clear the house of the family; and by cleansing, fumigating, and ventilating the apartment of the invalid, and other parts of the house, more is accomplished towards recovery than by concentrating large numbers together in a hospital; for the shock which is inseparable from removal often operates prejudicially on those over whom collapse is hovering.

There are duties devolving on the rich; and unless at this crisis these duties are performed, the affluent will enjoy no immunity from the visitation. It is the breeze which comes laden with pestilence-miasm, gathered in its way from the straw pallet of the neglected and famishing wretch who occupies one of the rich man's cots, which, through the jalousied and draperied rich man's window, shall bear to the loved and tenderly nursed inmates the message of the angel of death. We must as a profession unflinchingly proclaim to the rich man his moral obligation, and fail not to awaken his fear, if no other than selfish interest can arouse him to duty. Where water is supplied by public companies, we should urge on the authorities the necessity of some arrangement by which the poorest hovel shall be now at least freely supplied with this greatest necessary of life.

Of the positive antidotes, these are the main—fresh air, free ventilation, pure water, and wholesome food; of the negatives—freedom from anxiety, and from undue toil. The former being present, and the latter away, cholera will in vain seek for its accustomed haunts: the nidus will then be destroyed; we shall have chained the spirit of devastation, and lured it to its own destruction.

But, as we write, mournful prognostications of neglected want, of putrid exhalations, of foul dwellings, crowded with rage, and peopled with penury, with idleness, and with want, arise before us: we tread in imagination the sickening alleys and courts of our great towns, and feel again the physical and moral depression they have before produced.

The hand of the monster is again upon us, and we have again to struggle in its mortal grasp, as beginning where other diseases end—in death. It proclaims in the daily prints that time has diminished nothing, if indeed it has not increased its fatality. If we cannot arrest its coming, let us at least use the present opportunity to make us familiar with the tactics of our grim antagonists. If the profession are true to themselves, this visitation will determine its character, and point out the means for its cure. Let every practitioner tabulate *every* case, whether of cholera, diarrhoea, or cholericine, with the treatment adopted. So as accurately to fix data upon which conclusions may be safely based, we would strongly urge upon every medical man the desirability of adopting for himself *one* plan of treatment, and in every case, unless for good reasons to the contrary, persistently carrying it out. We shall thus, in place of the vacillating and uncertain reports which lead to no practical issue, have at our disposal a mass of facts and data from which a sound judgment can be derived, and the true laws of cholera be deduced.

We have no words to express the importance we attach to the conduct of our medical brethren at this emergency. It is one of those occasions when the profession is looked to for counsel, for guardianship, and help. The public will expect "every man this day to do his duty"; and we feel that from every heart there is but this one response—"Ready, aye ready".

THE CHOLERA, THE ASSOCIATION, AND THE ASSOCIATION JOURNAL.

THE steady march of Cholera from its eastern home, and its actual encampment in many of its old and familiar European haunts, at present awaken the anxieties and the fears of the public with as much freshness as if some new and unexpected calamity had occurred. But the medical profession can mingle no surprise with its sorrow: for nothing has happened which its wise men have not foretold would take place, unless better defences were prepared against the invader, than those which now exist. The advance of the disease over vast continents and tracts of country differing widely in climate and geological formation, and its progress during different seasons and different meteorological conditions, make it sufficiently evident that there is a pestilential something which can find a way for itself, be it by the land, by the water, or by the air. But the history of the past teaches us another and a more cheering lesson; for it assures us that although cholera may spread itself over a village, a city, or a kingdom, yet in some of the embraced localities it will be unable to procure a single victim, while its carnage will be terrific in those situations where men dwell among cesspools, foul privies, untrapped sewers, and graveyards—

"Where putrefaction into life ferments,
And breathes destructive myriads."

As the representatives of the medical profession we cannot give utterance to surprise; but though almost weary with the cry, we must once more lift up our lamentation and our complaint that, in this enlightened age, scientific medicine should still be refused its high and its rightful place in the statesmanship of England. For a time, but not for ever, can this complaint be disregarded.

Descending from what the State ought to do, to what the Association can without State assistance accomplish for humanity, let us in a few words state the kind of information regarding cholera which is wanted; and which we desire to disseminate through the medium of this Journal.

In the first place, we respectfully submit to our colleagues that a retrospect of the past shows that no advantage can be obtained by filling Medical Journals and Newspapers with defective histories of cases, and laudations of specific remedies. With both, the archives of medicine are encumbered, to the notorious discredit of the majority of those authors by whom this rubbish has been accumulated. What we wish to preserve in our pages, is a *series of authentic histories of every case of every disease occurring during a cholera outbreak within a given period and within a given district, accompanied by as complete an account as possible of the daily meteorological condition of the atmosphere*. From such data only can the natural history, the pathology, and the right treatment of cholera, be discovered; and, if such data there are very few practitioners among us who cannot contribute something useful, if they observe and report what they see with faithfulness and accuracy.

To those who wish to contribute to this Journal their experience of the threatened visitation, we would recommend the perusal of the article on Medical Meteorology in our number for the 26th of August, the circulars issued in 1849 by our own Association, by the College of Physicians, and by the Western Medical and Surgical Society of London. As these valuable documents are as appropriate now as when they were first published, we reprint an article in which they are embodied, from the *London Journal of Medicine* for November 1849.

**"FACTS ASKED FOR, ON WHICH TO ESTABLISH THE TRUE PATHOLOGY AND TREATMENT OF CHOLERA.—
MOVEMENT IN THE PROFESSION.**

"The Royal College of Physicians of London, the Provincial Medical and Surgical Association, the Western Medical and Surgical Society of London, and we rather think some other bodies, have issued important circulars, calling for information on the subject of cholera. All, most properly, ask for *facts apart from theory or opinions*. In reprinting the documents which have been issued, we would very earnestly impress upon the profession the duty which is now laid upon every member, to come forward with such a contribution to the general store as he may be able to give. We would also suggest that the different bodies might, perhaps with great advantage, co-operate, and issue one, in place of separate digests of information. Might not the Provincial Association, for example, have a representative in the Cholera Committee of the College of Physicians? with which committee, we think, the arranging and digesting of the reports might safely be left. From the subjoined circulars and queries, we feel confident that a committee better fitted for the duty could not be found. A general co-operation of the whole profession with the College of Physicians is what we would like to see. If we cannot combine as political bodies, let us all join, heart and soul, in this great pathological inquiry. Our broken ranks and paltry jealousies deprive us of our proper social position, and of our facilities of enlarging the boundaries of science. The present occasion offers an opportunity of union, which, if made use of, may lead men to know and appreciate each other more than they have yet done, and thus tend to good in many ways.

"COLLEGE OF PHYSICIANS: THEIR CIRCULARS.

"Royal College of Physicians, Pall Mall East,
6th September, 1849.

"SIR,—The Cholera Committee have instructed us to address you again, for the purpose of explaining the object of the resolution transmitted to you on the 6th ult., and of offering some suggestions as to the mode in which your co-operation could be most efficiently rendered.

"The opinions of the profession are divided on many points relating to the pathology and treatment of cholera; and it is not to be expected, that the doubts and discrepancies existing will be finally settled by the evidence which any individual member of the profession may adduce. But the committee have a confident hope, that valuable and conclusive results, in regard to at least some of the disputed points, might be obtained, by collecting and comparing the observations of hospital physicians, and of the many other members of the College who have practical experience in the present epidemic.

"Such a method of inquiry appears to be especially applicable, and indeed indispensable, in any endeavour to estimate the relative values of the various modes of treating cholera, respecting which the evidence is at present so conflicting. With the co-operation of the members of the College, the committee may, it is hoped, in some cases, be able to fix the kind and amount of benefit derivable from particular remedies or plans of treatment; they may establish the superiority of some remedies; and, with regard to others, they may show that their use ought to be at once abandoned.

"The following list includes the principal modes of treatment hitherto recommended. It seems desirable that every member of the College, who has the necessary opportunity, should submit one or more of these to a systematic trial in a series of cases. But the committee request that you will communicate to them any observations you may have made, on the effects of other remedial means not included in this list:—

"Calomel, in large doses; in smaller and frequent doses.

"Calomel with opium.

"Opium in large doses.

"Ammonia; alcoholic liquids; essential oils and aromatics; camphor and musk.

"Acetate of lead; sulphate of copper; the vegetable astringents.

"Quinine; arsenic; iron.

"The saline plan, as recommended by Dr. Stevens.

"The tartarized antimony plan, as recommended by Dr. Billing.

"Emetics.

"The free administration of cold water and ice; the cold bath and cold douche.

"The application of the 'wet sheet'.

"Injection of saline or other fluids into the veins.

"Bleeding.

"Electricity.

"With regard to the form in which your observations on the results of treatment may be communicated, the committee would merely suggest that, with a view to the subsequent comparison of the facts contributed by different observers, a statement, not merely of the number of cases treated with each remedy, and the main results, but also of some particulars of the cases, is desirable. The following points appear the most important, with reference to the object in view:—

"The age and sex of each patient.

"The period of the attack at which the treatment was commenced.

"The severity of the attack, as indicated by—

"1. The pulse.

"2. The state of the surface, especially of the face and extremities, as to temperature, moisture, and colour.

"3. The appearance and amount of the intestinal evacuations.

"4. The existence and degree of urgency of the vomiting and cramps.

"5. The state of the urinary secretion.

"The apparent immediate effect of the remedy on the symptoms.

"The duration of the state of collapse, whether fatal or not, after the commencement of the treatment.

"And, in cases of recovery from collapse, the supervention or not of the state called the 'consecutive fever'.

"The preceding observations have reference, more especially, to the treatment of the disease in the stages of impending and complete collapse. But the committee would gladly learn the results of your experience relative to the means of arresting the diarrhoea, which, in many instances precedes the stage of collapse, and of restoring the healthy action of the kidneys, when collapse has been recovered from. (See the Queries, Nos. 6 and 10.)

"Lastly, the committee request that you will communicate to them the results of any inquiries you may have instituted into the morbid anatomy of cholera, or into the chemical and microscopic analysis of the blood and secretions in the different stages of the disease, and any general observations on the pathology of cholera. The series of queries, appended to this letter, embraces some of the more important questions, which might be elucidated by the combined experience of the members of this College. But it is not desired by the committee,

that, in any communication with which you may favour them, you should limit your remarks to the subjects of those queries.

"We are, sir, your obedient humble servants,

"WILLIAM BALY, } *Secretaries to the*
"WILLIAM W. GULL, } *Cholera Committee.*

"**QUERIES.**

- "1. Can you communicate to the committee any facts observed or investigated by yourself, which appear to you demonstrative of the contagious or infectious nature of cholera, or of its communicability in any way?
- "2. Can you detail any facts illustrative of the influence of deficient ventilation, damp, foul air, and bad water, respectively, or of other external circumstances, in determining or favouring the production of cholera?
- "3. What are the particular states of body or mind, which, according to your experience, have most frequently predisposed individuals to be attacked by the disease?
- "4. What are the groups of symptoms which have preceded the full development of the attack of cholera?
- "5. Have you observed any distinctive marks by which diarrhoea, about to pass into developed cholera, may be recognised?
- "6. Does it accord with your experience, that cholera, in the stage of 'serous' or watery diarrhoea, can with facility be checked? What means have you found most effectual in attaining this object?
- "7. Have any facts come under your notice, which, independently of theoretical views, should elucidate the question, Whether the affection of the intestinal mucous membrane in cholera is the primary disease, or one of its secondary effects?
- "8. Can you furnish the committee with the particulars of cases, in which the rapidity of the fatal collapse has borne no relation to the amount of fluid discharged from the blood-vessels, either through the intestinal mucous membrane, or through the skin?
- "9. What are the pathological conditions which you have observed in the 'consecutive fever'?
- "10. What means have you found most successful in re-exciting the function of the kidneys, after the stage of collapse has passed?

"Royal College of Physicians, Pall Mall East,
13th October 1849.

"SIR,—We are instructed by the Cholera Committee to transmit to you the accompanying copies of the letter issued on the 6th of September, and to request that you will distribute them amongst those members of the profession in your neighbourhood, not members of the College, who have had the largest experience in the epidemic now subsiding. Any aid which those gentlemen may afford the committee, in furtherance of the objects indicated, would be received as an obligation.

"The committee are also desirous of obtaining your co-operation in a special inquiry respecting the origin and mode of propagation of the cholera. They believe that much might be done towards the elucidation of this important question, by collecting authentic information in regard to the first cases of the disease in the several towns, villages, and public institutions throughout England. They have accordingly directed us to submit to you the subjoined queries, and to beg the favour of your obtaining for them as detailed and precise answers as may be possible:—

- "1. Had the person first attacked with cholera in recently been in an infected place? or had he received into his house clothes or other articles, which may have conveyed infection? or had he been in contact with strangers coming from an infected locality?
- "2. If the disease appears not to have been introduced in any one of these ways, is it possible that the drinking-

water was the means of conveying the infection, by its being contaminated in its previous passage (as a river or canal) through infected places?

- "3. What was the character of the part of in which the first case occurred, as regards elevation, drainage, supply of water, density of population, ventilation, and cleanliness?
- "4. Did the first few cases occur simultaneously? or after what intervals did they succeed each other?
- "5. Is there any evidence or probability of there having been communication, or near approach, between the first patient, or patients, and those next affected?

The following queries have reference to the communicability of the disease, but do not relate especially to the first cases:—

- "6. In the instances where several cases have occurred in the same house, have they been simultaneous or successive?
- "7. Have any persons attending on cholera patients, or employed to wash the clothes or bed-linen of such patients, been soon afterwards attacked with the disease?
- "8. Where several persons in one house, or in contiguous houses, have been attacked, in a district otherwise free from the disease, has it been discovered that the water used for drinking had been contaminated by a sewer, drain, or cesspool? or have any other causes appeared, which would explain the particular limitation of the disease?
- "9. Can you learn that the disease has apparently been conveyed to neighbouring healthy places, by infected persons leaving?

"In conclusion, we have to ask of you the favour of an early reply to the present, as well as the previous, letter of the committee. It is desirable that all communications should be sent in by the 15th of November, or as soon afterwards as possible.

We have the honour to be, sir,

"Your obedient humble servants,

"WILLIAM BALY, } *Secretaries to the*
"WILLIAM W. GULL, } *Cholera Committee.*

"It would be very difficult for the most hypercritical to object to a phrase, or even a word, in the above documents. They have evidently been framed by physicians, who have not only read and reflected much upon the pathology and treatment of cholera, but who have also had extensive clinical experience in the disease. One or two additional points of information may occur to some, we doubt not; and perhaps it would have been well to have included a request for any facts connected with cholera which the respondent might possess, even though not embraced in the queries. Some might have observations to communicate on the sequelæ of cholera, upon the type of other diseases during the epidemic of cholera, upon recovery from the cold stage by those who had no medical treatment: and others might imagine they had statements of value to make regarding other medicines than those specified, among which we might cite as examples, sulphur, and the camphor chloroform mixture, remedies which have been largely used by some, especially for the cramps. In reference to the calomel treatment in the stage of collapse, it would be well for the stools to be examined, for the purpose of determining the extent and rapidity with which the unaltered drug is washed out by the serous discharges.

"It is not merely desirable, as stated by the secretaries of the cholera committee of the College of Physicians, to have particulars of the cases in which each mode of treatment was employed—it is absolutely essential. No statement of treatment is worth anything, unless accompanied by a full detail of each case in which it was tried,—recorded, moreover, not from memory, but at, or immediately on quitting, the bedside of the patient.

"The PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, by means of its wide spread and numerous members, possesses

extraordinary facilities for obtaining a correct digest of the history of cholera in the provinces. The following is a copy of the official paper:

"INQUIRY ON CHOLERA. In compliance with the resolution passed at the annual meeting held at Worcester, the annexed questions have been carefully framed; and it is earnestly requested by the Council that the members of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION will assist in this laudable purpose, by forwarding as full and complete a series of answers as possible to Mr. Hunt, 26, Bedford Square, London, who has kindly undertaken the inquiry.

CHARLES HASTINGS,

"President of the Council.

QUESTIONS.

1. "During the prevalence of the epidemic, has your own neighbourhood, town, or district, been *exempted* from the visitation? If so, can you mention any local circumstances which may account for the exemption? Was the district healthy during the visitation of the cholera about the year 1832, and did circumstances then exist which may be supposed to have protected it?
2. "If the cholera* has appeared in your district, how many cases have you seen? how many of these have been fatal?
3. "When did the disease break out, and how long did it prevail? Please to state generally whether many persons were simultaneously attacked, or otherwise; and whether it commenced contemporaneously in more than one site in the same town or district, or whether it appeared to spread from one point only. Were there any peculiar circumstances observable in its local character, or in the course or direction of its advance, which may throw any light upon the important question, whether the disease be of a *contagious*† nature or otherwise?
4. "Have you invariably been able to trace the disease to *local impurity of the atmosphere*, or have you seen it attack persons living in a pure air, apart from graveyards and other sources of putrefaction, in well drained and well ventilated dwellings? In cases of the latter description, if any have been observed, has there been any intercourse with the sick which may tend to establish the doctrine of *contagion*, or the reverse?
5. "Did the cholera appear in your neighbourhood *with* or *without* the general and contemporaneous appearance of the *milder forms* of disease, diarrhoea, bilious cholera, etc.? Has dysentery or typhus been prevalent or otherwise?
6. "Were its ravages indiscriminate as to personal vigour, age, sex, station, occupation, etc.; or might the attacks be traced to some *predisposing personal cause*, as weak bowels, intemperance, debility, fear, errors in diet, uncleanly or sedentary habits, or impaired health from any cause?
7. "Were 'premonitory' symptoms of general occurrence, or did the disease frequently appear suddenly in its malignant form, with violent cramps, vomiting and purging, 'rice water' dejections, and rapid collapse?
8. "Did the symptoms differ from those generally observed and frequently described? Had the disease any peculiar type, either of mildness or malignity?
9. "Are you aware of any exempting circumstances, of any description, which have uniformly protected certain individuals

* "In using the term *cholera*, or in responding to any question concerning it, please to adhere strictly to this definition:—The term *cholera* shall be restricted to that so frequently fatal form of the disease in which there are vomiting, purging, cramps, and 'rice-water' evacuations, and to that still more formidable state of collapse unaccompanied by these symptoms; that the term *Bilious Cholera*, shall apply to the disease formerly called *Cholera Morbus*, in which there is both vomiting and purging of bile, with cramps; and that the term *Diarrhoea* shall be confined to those cases in which there are simply frequent and numerous fluid alvine discharges, without either vomiting or cramps."—*Prov. Med. and Surg. Journ.*, Sept. 6th, p. 490."

† "A house or district may be infected, so as to spread a disease not strictly contagious. Respondents are therefore requested to confine the latter term to evidence of communication by personal approach or contact."

from the disease,—such as trades, habits, diet, etc., not inclusive of local habitation?

10. "Can you throw any light on the *physical origin* or remote cause of the recent or former visitation? Are you able to say, from your own observation, that the general symptoms and history of both are similar? Have you instituted any researches into the density, humidity, temperature, or electro-magnetic phenomena of the atmosphere; especially, have you inquired into the relative quantity of ozone existing in the air during the prevalence of this epidemic or the former visitation; and have you compared it with the proportion observable during the last visitation of the influenza? Have you observed the progress of the cholera to be arrested by storms, wind, or rain?

11. "Have you made any *post mortem* examinations of fatal cases of cholera, and with what result? Do you know of any circumstances which justify the immediate interment of the dead? Did you ever observe cholera patients show signs of organic life for hours or days after apparent death?

12. "Can you describe any method or principle of TREATMENT which has proved successful in so large a number of cases of *cholera*, as to commend it to universal adoption? If so, has not the method frequently failed in other hands, and can you explain the cause of failure?

13. "What mode of treating the epidemic *diarrhoea*, and premonitory symptoms generally, have you found most successful?

14. "Can you suggest any means of preventing or arresting the spread of the disease in the event of any future outbreak?

15. "What is your opinion as to the propriety of removing the inhabitants who have not taken the disease, from the infected dwellings, to houses of refuge, in situations where the presumed causes of the disease are not in operation?

"WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON. This Society deserves very high praise for the zeal and excellent direction of its labours in connexion with cholera. It has also the merit—no small one—of having been the first body in the profession to come forward with a regular and scientific plan for observing and reporting cholera cases.

"About the end of September 1848, when the first cases of epidemic cholera occurred in London, the first steps were taken; and on the 15th of October, a very full meeting was held, to consider what plan ought to be pursued. It was universally lamented, that the epidemic of 1832-3 should have left behind it so little authentic and positive information; and it was anxiously inquired, whether the Society might not hope, by timely exertion, to derive more satisfactory results from the epidemic which was then evidently approaching. One way to do so seemed to be the obtaining records of such a number of cases as would justify conclusions from their analysis. But it was obvious, that these records would not be of value, unless they entered into considerable detail: and that, from practitioners actively engaged, such detail could neither be expected nor obtained, without the aid of some plan whereby their attention might at once be called to the points chiefly to be noted. There would be this further advantage, too, from an uniform plan, that the subsequent tabulation and analysis would be rendered much easier. These views were embodied in resolutions, unanimously agreed to, and made public through the *Lancet* and *Medical Gazette*, of October 21st and 27th respectively; and a committee was appointed to draw up the plan. The committee devoted itself incessantly to its labours, and early in November the plan was completed.

"The tabular form consisted of a folio half-sheet, one side of which was ruled to receive all the details of the case, under the heads of 'State of the countenance, and general aspect of the patient; state of the tongue; state of the skin; state of the pulse; state of the voice and respiration; character and fre-

* "See an article on the Causes of Cholera, by Mr. Robert Hunt, in the *Athenaeum*, Sept. 1, 1849."

quency of the vomiting; of the stools; of the cramps; state of the urinary secretion; state of the nervous system,' etc. etc. The paper was so ruled as to admit of eight separate observations on each of these points; it being considered that this number would be sufficient for a protracted case, while, in a rapid case, not more than two or three could be expected. On this side of the sheet, a space was allowed for preliminary inquiries, including the occupation, habits, previous health of the patient, as well as the symptoms, if any, exhibited up to the appearance of those characteristic of the disease, the locality in which he dwells, etc. etc. Another space was allotted for any general observations on the case which might occur. The other side of the half-sheet was divided into two portions; one intended for the record of the treatment pursued; the other for the entering the state of the organs at examination after death, where such was undertaken.

"A form, thus completed, was capable of comprising all the details of a single case. Several hundred of them were printed at the expense of the Society, and delivered (a certain number to each) to all the practitioners, whether members or not, residing in Chelsea, Pimlico, Brompton, Kensington, Hammersmith, Putney, and Fulham. Along with them, was sent a circular letter explanatory of the purpose of the Society, requesting that a record of each case that might come under the practitioner's care might be entered on the form, and returned to the Society for analysis; and desiring information of any kind which might throw light on the disease, especially on the circumstances attending its outbreak in any fresh locality; the existence or non-existence in each case of premonitory diarrhoea; its character and amount, the prevalence or not of ordinary diarrhoea, etc. etc. It was also requested that the specimens of the blood, of the matters vomited, and of the characteristic dejections, might be forwarded for chemical and microscopical examination. Such was the plan proposed for the investigation of the disease. In carrying it out, the Society was obliged, for obvious reasons, to limit its operations to the district mentioned—that in which the members, and those with whom they could more readily communicate, resided; but the hope was entertained that the plan would be adopted, or improved upon, by other metropolitan and provincial societies, acting each within its own district. For this purpose, copies of the tabular plan were forwarded to all the London medical societies, and to such of the provincial societies as desired them; and official letters were written by Dr. Seaton, the Secretary, and published in the *Medical Gazette* of October 27 and November 17, and in the *Lancet* of corresponding dates. If the hopes had been realised, there can be no doubt that there would now have existed materials for a far more complete history of the epidemic, based on more comprehensive data, than any we are now likely to attain. The Medico-Chirurgical Society of Bristol alone, which has since earned for itself so much honour in reference to cholera, recognised the value of the scheme, and adopted, with slight alterations, the printed forms for cases.

"As an addendum to what we have said in reference to the plan and exertions of the Western Medical and Surgical Society, and its able and zealous Secretary, Dr. Seaton, we subjoin the following communication from Mr. F. S. Haden, which appeared in the *London Medical Gazette*, of October 19th, 1849.

"A PLAN TO INSURE RAPIDITY AND UNIFORMITY IN CHOLERA CASE-TAKING. Sir,—In October 1848, the Western Medical and Surgical Society of London issued a tabular form for uniformly reporting cases of cholera. In this form, a space is allowed for preliminary inquiries—for successive observations of the symptoms in detail—and for recording the condition of each organ at an examination after death.

"I have considered, however, that practitioners desirous of noting cases of cholera would have their labours facilitated, if a similar list of symptoms, inquiries, etc., were printed, as is here done, with a letter or number prefixed to each. The letter or

number being taken to represent the question or symptom against which it is placed, the observer would then merely have to write on a piece of prepared skin or paper, e.g. '2. anxious'; '3. contracted'; '4. moist'; '5. cold', etc.; and on the reverse of the skin, the prescription. Much time would thus be saved at the bedside, and the case could be written out in full at leisure, or entered upon the larger form of the Society.

"I am, Sir, your obedient servant,

"FRANCIS SEYMOUR HADEN.

"Number of Case—Date—Name and Occupation—Sex—Age—Habits and Previous Health—Residence—Locality, high, low, moist, or dry—Proximity to Rivers, etc.—State of Drainage.

"A—Supposed exciting cause of the attack. B—Diet within the preceding twenty-four hours. C—State of stomach. D—State of bowels. E—Other ailments. F—Medicine already taken.

"CHARACTERISTIC SYMPTOMS. 1. *Hour of first appearance?* 2. *Countenance*—Expression of? 3. *State of the Pupils?* 4. *Tongue*—appearance and condition of? 5. *Temperature of?* 6. *Skin*—Generally or locally, appearance of? 7. *Condition of (as to secretion)?* 8. *Temperature of?* 9. *Pulse*—Volume and character of? 10. Number of, whether felt at the wrist? 11. In the axilla? 12. In the carotids? 13. *Heart*—Stethoscopic examination of? 14. *Voice*—As to the tone and power? 15. *Respiration*—Frequency of? 16. Free or laborious? 17. Relative duration of inspiration and expiration? 18. *Breath*—Temperature of? 19. *Vomiting*—Its character and frequency? 20. *Stools*—Their quantity and frequency? 21. Their character, colour, and consistence? 22. *Cramps*—Nature, frequency, and parts affected? 23. *Thirst*—Urgent or tolerable? 24. *Urinary Secretion*—State of? 25. *Nervous system*—Affections of? 26. Degree of consciousness? 27. Deafness? 28. Noises in the head? 29. Loss of vision? 30. Convulsions? 31. *Termination of the case*—In gradual or sudden recovery? In consecutive fever, or in death?

"POST MORTEM EXAMINATION—HOURS AFTER DEATH. *External Appearance of the Body*. 1. Colour—temperature—rigidity? 2. Any muscular twitching after death? its duration?

"ENCEPHALON. 3. Degree of congestion? 4. Effusion, its nature and seat? 5. Other lesions?

"THORAX. 6. *Pericardium?* 7. *Heart*—Degree of rigidity and flaccidity of each ventricle? 8. Contents of each ventricle as to quantity? 9. Condition of blood as to fluidity and colour? 10. If fluid, does it coagulate on exposure? 11. *Lungs*—General condition and appearance of?

"ABDOMEN. 12. State of the peritoneum, and of the abdominal cavity? 13. *Liver*—Condition and appearance of? 14. *Gall Bladder*.—Nature and quantity of its contents? 15. *Gall Ducts*—Condition of? 16. *Stomach, duodenum, small intestine, cæcum, colon, and rectum*—Contents of respectively? Are they acid or alkaline? Condition of the mucous membrane of respectively (*with regard to appearance and state of glands*)? 17. *Spleen?* 18. *Kidneys?* 19. *Urinary Bladder*—As to contents, and degree of contraction?

"VASCULAR SYSTEM. 20. Aorta and vena cavae. 21. Pulmonary artery and vein. 22. Femoral artery and vein. 23. Hepatic, gastric, splenic, mesenteric, and renal arteries and veins. 24. General condition of whole vascular system, especially as to congestion, etc.

"We have given place to the above documents and remarks, because we feel that the members of our Medical Colleges and Societies require to be stimulated to the earnest observation of the disease, and to be reminded of the opportunities now afforded of making good use of their facts."

We do not expect that every observer can afford the time for reporting cases in the detailed manner suggested by the Western Medical Society; but that the reports of dispassionate observers may be capable of instructive comparison, we have no doubt.

the favour of our contributors employing at least the general outline of that system, which is the most complete and also the most easily followed with which we are acquainted.

In conclusion, let us warn our friends against allowing their philanthropy and their scientific ardour to be chilled by the indifference with which the public look upon that patient plodding by which only medical truth can be attained. It may be disheartening to see impudent nostrum vendors realising wealth at every corner by the sale of so-called cholera specifics, while the skill of honest and enlightened men is not appreciated; but then we must moderate our disappointment by remembering that the rewards in store for those who successfully pursue medical and hygienic inquiries are of a nobler kind than pelf and personal aggrandisement, while at the same time they by no means preclude pecuniary advantages which often, though not always nor uniformly, flow from a well earned fame. As regards the profession, we cannot doubt that it is by establishing for itself undeniable claims upon public gratitude, and at the same time scorning to rise by the pseudo-philanthropy of indiscriminate gratuitous advice, that it shall ultimately obtain that amount of social and political influence which the well being of the community requires, and which Medicine is entitled to receive.

In our next, we propose to speak of the formation of local Cholera Committees by members of the Association, and other respectable practitioners willing to cooperate with them. In the meantime, we now announce our willingness to arrange and digest all the available information which may be transmitted to us, for the purpose of forming the basis of an authentic history of the epidemic.

FINANCE: THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

How true is the observation of Lessing, that there is no descending to the people; that, to be successful, whether as individuals or as companies, whether singly or collectively, every rung of the ladder must be trodden, and confidence gradually, and step by step, be acquired. Does not the experience of our readers, who have fought their way resolutely, day by day, to the position they occupy in life, confirm the truth of this theory? For however *profanum* we may affect to consider the *vulgus* of the world, we cannot, if we look back, but see how all things are by its mighty dictum ordered and disposed.

Our Association is but another exemplification of this law, added to another law of equal truth and as enlarged import—that the atom, however in itself insignificant, by aggregation becomes a mighty mass, potent for good, and not always without an influence for evil; but restrained and curbed by the mighty truth, that evil is in itself self-destructive. Beginning humbly with comparatively few members and with small funds, it has become a vast and a noble organisation, slumbering oft, and oft disregarded, but with its giant strength waiting but for occasion of development to attest its power. It has gone through its phases of infancy and youth to a mature age, and is destined to exercise an influence, only now advancing to acknowledgment, which shall be felt wherever the progress of civilisation demands the services of the practitioner of the healing art. It has been afflicted, and has learnt wisdom; it has progressed slowly, and by many unheeded, until to-day it is the strongest agency which bears upon medical science,

whether that science be viewed as a system of politics, of philosophy, of arts, or of ethics. It comes not to disturb and to uproot the combinations and usages of the past, but to modify, to conserve, and to aid them. It is not the peasant, wishing the mighty Ganges to flow through his garden, astonished to find that the fulfilment of his wish brought as its consequences destruction and devastation; but the wiser friend, who asked only for the rill from the neighbouring brook, whose healing waters, in their gentler flow, fructified, nourished, and fertilised his land. It proposes no sweeping change or mighty reform, for it has learnt that to alter is not always to amend; and that, in medicine, true reform is always conservative; but it provides a careful protection, a watchful guardianship, and an ever ready help. These are the advantages which our Association now proffers to its members, and which it hopes soon to be able to supply with a more powerful and a more liberal hand.

But we are met at the threshold of our endeavours by *the necessity for funds*; and we have in a former article endeavoured to show that, to provide for unity of purpose and intelligent and combined action, with all the other advantages which combinations bring in their train, a Journal to explain the views of the members of our Association becomes a necessity; and we believe we have proven that as much pecuniary as correlative benefit arises to the members from this adjunct to our Association machinery.

With our present number of members—say 1900—£300 is left, after paying Journal expenses, for other Association purposes. This we would distribute in the following manner, always premising that in so doing we take no account of the £691:3 contributed during the year to the Medical Benevolent Fund, presided over by Mr. Newnham. We should thus have for

Annual Meeting	35
Secretary	105
Committees, Printing, Stationery, etc., independent of the Journal Establishment	100
	£240

leaving £60 for other applications of the Association funds. These applications might with advantage be extended in many directions. An important question, for example, has been suggested to us; namely, How far the Association, as a body, might use its influence to protect the rights of its individual members, when subjected to wrong and injustice? We can conceive of many ways in which the future of our Association might be made to bear upon the defence of the just claims of its members; and, in questions purely professional, not only could the Association render much aid, but the mere fact of its influence being used would materially tend to prevent the recurrence of similar acts of oppression.

We have been much pleased at noticing the formation of an Irish Medical Association, on the model of our own. We cannot but consider this event, and the establishment of Medical Associations and Medical Association Journals in France and Spain, as the best sign of the times, medically considered—the extension of Associations, all tending to draw closer together the bonds of fraternal unity and brotherhood.

We are induced in this place to particularly notice the Irish Medical Association, from a feature in its programme, where it offers annually a prize to the member who shall write the best essay on the progress of medicine and surgery during the year. This idea we might with advan-

tage at no very distant day adopt in our own Association; and still be able to lay by something as a sinking fund, the interest of which (with the principal if necessary) to be devoted to those contingencies to which the best regulated associations must always be more or less subject.

It is true that the star of our Association is in the ascendant everywhere, and that on all sides we are met by aspects of encouragement. The contemplated junction of the Yeovil and Crewkerne Medical Society with our Association will be found reported in our columns of to-day; and the accession to our ranks of individual practitioners goes on unceasingly. Now, therefore, is our opportunity of permanently establishing financial security, and enlarging the sphere of our operations.

But, independent of stated fees, nearly £700 has been contributed during the year by the Association and its friends to our Medical Benevolent Fund, a Fund unostentatiously and in secret relieving the direst distress—distress the greater, because falling on those so ill prepared for its reception. Nursed in the lap of comfort, oblivious of the future, and living but for to-day, how many of our wives and daughters are at this moment in want of the merest necessities of life, kept but alive, or from the Union Workhouse, by the almsdeeds of this Fund—a small token of respect from the more fortunate of an ill requited profession, to the afflicted families of their unfortunate brethren. Viewed but financially, ours is in truth a noble Association. It is indeed matter of gratulation, that from the hard working and ill paid medical men of these realms, so much is subscribed to enlarge the usefulness and increase the applications of medical science. We seek to improve the condition of suffering humanity by increasing our own means of usefulness; and when by long continued toil our brother is disabled from further exertion, and when the hard wind of adversity blows on his unprotected family, we afford some little covering, and though small and temporary, at least a partial shelter from its bitter and biting blast.

Our financial condition is sound and healthful; but it will only continue so while we have on the part of our members the same desire to promote the general good, and the steady continuance of efforts to extend the usefulness of our labours. Our Association must not resemble the mighty endogen of the tropical forest, whose growth from within in time bursts through the encircling but false and treacherous envelope, and causes by its inherent force its own destruction. But like our own mighty wood monarch the oak, receiving from without new accessions of strength, it must continue to grow until it embraces within its genial pale every practitioner of the healing art; liberally receiving aid and encouragement, it must in return liberally impart the solid advantages of increased means and opportunities for usefulness, and of support and protection in the faithful discharge of duty.

THE CASE OF FENNEL v. ADAMS.

We trust that Mr. Lord's appeal (published at p. 837 of last number) may be successful in procuring subscriptions sufficient to defray the expenses to which Mr. Fennell has been subjected, in obtaining a public inquiry into the accusations which were groundlessly made against his professional character. To the medical practitioner, character is capital: and he who cannot preserve it from the spoiler is certainly a ruined man. Mr. Fennell felt this; and he

manfully and successfully vindicated his reputation by the only method which he could employ. The pecuniary expenses incurred are, however, more onerous than Mr. Fennell can easily bear. This, we think, would be in itself a very sufficient reason for a subscription being opened to defray these costs; but a more potent reason for our united support of Mr. Fennell lies in the moral good which will result from the public perceiving that medical men are able and willing to associate together for the protection of an injured brother. We therefore ask our friends to come forward with their donations, not merely as an act of kindness to Mr. Fennell, but much more as an act of benefit to the whole profession.

NEWS AND TOPICS OF THE DAY.

JUDICIAL ESTIMATION OF HOMŒOPATHY IN FRANCE. The *feuilleton* of *l'Union Médicale* for September 3 contains an account of an action brought at Toulouse, on 12th August, by a homœopathic practitioner against one of his patients, to recover the sum of eighty francs. The particulars of the account were as follows: Nineteen visits, 40 francs; opening an abscess in the finger, 5 francs; fifteen cauterisations and dressings, 15 francs; medicines, 20 francs.

The defendant, M. D., asserted that he had agreed to pay the homœopath, M. X., two francs for each visit, and to add two francs for the medicines, making forty francs; and he considered that this was paying very dearly for globules, even supposing the medicine to be worth five francs per grain. He further objected that M. X. was a physician and not a druggist; and was consequently not authorised to charge for medicines. Relating the case of one of his children, for whose illness he had consulted M. X., he thus ingeniously exposed the duplicity of the homœopaths:

"I called in M. X. He entered on the subject by developing to me the beautiful principles by which homœopathic practitioners are led. 'We never bleed', he said. 'Why deprive nature of the blood which she has formed to nourish the organs? We perform no surgical operations.' 'What, then, do you call surgical operations, you who open abscesses and employ cauterisation? Ah! you have doubtless a double: one of you is a physician, making me pay for the visits; the other a surgeon, requiring payment for cauterisation and dressing. You have laid a snare for me; for I did not call you in as an allopathic physician, and you have deceived me. You cannot escape from this dilemma. As a homœopathic physician, your practice should have been homœopathic. But you have practised allopathically; you therefore owe me damages, for you have acted otherwise than was agreed on.'"

M. D. then went on to contrast the difference between homœopathic and regular practitioners, referring to the case of another of his children, who had been under the care of M. X., but continued to become worse. He then called in an allopathic practitioner. The charges of the latter were eighty francs for fifty-seven visits, without any charge for medicine. After some time, M. X. called upon M. D. to represent to him that allopathic treatment would not cure his son.

The judge decreed that M. D. should pay the sum of forty francs, which he had offered to M. X.; he also condemned M. X. to pay the costs, estimated at 15 francs 80 centimes, not inclusive of the costs of declaration of the present judgment; as well as a fine for contempt of court, in not appearing at the trial.

EPIDEMIOLOGICAL SOCIETY: CHOLERA. The Cholera Committee of the Epidemiological Society, feeling the importance of obtaining authentic information from medical practitioners in all places where the cholera may appear, especially with reference to the origin of the early cases, has invited communications to be addressed to either of the Secretaries of the Committee, Dr. Bryson, 8, Duke Street, St. James's; and Dr. McWilliam, 14, Trinity Square, Tower Hill.

MEDICAL BENEVOLENT COLLEGE. At the last meeting of the Council, held at the Hanover Square Rooms, Edward Henry Sieveking, M.D., was unanimously elected Honorary Secretary of the College, vice Henry Tudor Davies, Esq., resigned.

FACTS AND OPINIONS RELATING TO TUBERCULOSIS, WITH COMMENTARIES.

By HENRY ANCELL, Surgeon.

NO. I.

HAVING recently published a voluminous Treatise on Tuberculous Diseases, there may be some surprise that I should so soon again urge the subject upon the attention of the profession. There have subsequently appeared several important statistical reports, and some interesting papers and monographs; and my work has been reviewed by all the more influential medical, and some literary periodical journals, eliciting the discussion of certain disputed points. I have carefully collated such of these as have been brought under my notice, with a view to ascertain the facts and opinions they contain, and how far they tend to confirm or to correct the principles and practice inculcated in my own book; and, since it will impose on me very little additional labour, I purpose, in a few papers, to lay the results of this investigation before the readers of the ASSOCIATION JOURNAL.

The present paper will embrace, mainly, statistical facts: and I commence with the statistics of tuberculous diseases in London, for the year 1852, from the Registrar-General's *Summary of the Causes of Death*, very recently distributed. My work on tuberculosis contains similar records as late as the termination of the year 1851.

The population of London, as estimated in this report, to the middle of the year, was 2,420,619; the total deaths were 54,213. The following table shows the deaths from tuberculous diseases:—

TABLE I.

	QUARTERS ENDING				Total.
	March 27.	June 26.	Sept. 25.	Dec. 25.	
Scrofula	131	124	106	86	447
Tabes Mesenterica	198	194	279	167	838
Phthisis	1811	1790	1672	1662	6935
Hydrocephalus ..	448	437	406	304	1595

In all, 9,815. This gives the proportion of deaths to the population living:—

From Tuberculosis in the aggregate 1 in 246.6
 „ Scrofula 1 in 5413.
 „ Tabes mesenterica 1 in 2769.
 „ Phthisis 1 in 349.
 „ Hydrocephalus 1 in 1517.

And, to the total number of deaths, the proportion is:—

From Tuberculosis 1 in 5.5
 „ Scrofula 1 in 121.2
 „ Tabes mesenterica 1 in 64.6
 „ Phthisis 1 in 7.8
 „ Hydrocephalus 1 in 35.7

It thus appears, that tuberculous diseases were in a trifling degree less fatal in 1852 than in 1851;* since, in the latter year, by the tables of the Registrar-General, the deaths from these diseases, in the aggregate, were 1 in 5.6 of the total number of deaths; and the deaths from phthisis amounted to 1 in 337.8 of the population, or, as respects the total number of deaths, to the extent of one decimal point, they were 1 in 7.8; that is to say, the proportion was precisely the same.

We have before us, in the next place, the *Statistical Reports on the Sickness, Mortality, and Invaliding, among the Troops in the United Kingdom, the Mediterranean, and British America*, by Colonel Tulloch and Dr. Balfour; being a continuation of the reports, of which four volumes were previously presented to Parliament, and including the principal facts connected with the health of the troops for

the ten years subsequent to March 1837. My object with this highly important volume is solely to extract the vital statistics having reference to tuberculous diseases, although it contains equally interesting matter relating to other maladies. The contents of this volume are the more important, inasmuch as it furnishes information connected with our subject, derived from large bodies of men at the same periods of life, within the limit of fifteen and fifty years, and even, as respects a vast majority, between twenty and forty years of age, subject to nearly the same regimen and discipline, with habits of life extremely analogous, and generally very well known; the principal difference being, that they serve in separate localities and different climates.

The aggregate strength of the troops serving in the United Kingdom, for the ten years, was 266,680. The “Abstracts”, published with the report, contain very little notice of hydrocephalus or tabes mesenterica; these being, in the main, diseases of periods of life antecedent to the commencement of military service. In the whole force, during the ten years, only three cases of the former, and two deaths, are recorded; and the latter is not specified.

The cases of scrofula admitted into hospital were 1,078, with 15 deaths, viz.:

	Admitted.	Died.
Dragoon Guards and Dragoons	179	—
Foot Guards	147	2
Infantry of the Line	752	13
Household Cavalry	Not mentioned.	
	1078	15

Thus, the annual average admitted into hospital was rather more than 4 per 1,000, and the deaths 1 in 17,778.

The number of deaths from scrofula in the army, compared with the number of deaths from the same cause in the general population, is as 1 in 17,778 to 1 in 5,413. Two circumstances may be brought forward to explain this discrepancy: 1. The period of life for military service is not that at which scrofula is most prevalent, or most frequently proves fatal; this is shown by the statistics introduced into my work,* by which it appears that, in 1847 at least, the proportion of the male population, from fifteen to fifty years of age, who died of scrofula, was 1 in 6,673, and, from twenty to forty years of age, 1 in 6,744—the age of a vast majority of soldiers coming within the latter period: 2. The principal reason appears to be, that scrofula and its signs are grounds of exemption from military service.

Before we consider phthisis, it is necessary to state that, in the report, the aggregate number of *pulmonary diseases* as a class is given, and also certain groupings; and, since the deductions of the authors are founded in a great measure upon the statistical results thus obtained, I adopt the more important tables bearing directly on the subject of tuberculosis, with the addition of others framed by myself to elucidate particular points.

The following table will furnish, in the first place, a general view of the prevalence of disease of the lungs.

TABLE II.

The proportionate number of cases of disease of the lungs, viewed as a class, to the aggregate strength of the troops serving in the United Kingdom.

	Aggregate strength, 10 years.	Annual ratio per 1000.	
		Admitted.	Died.
Dragoon Guards and Dragoons	54374	152	7. 3
Foot Guards	40120	161	13. 8
Infantry of the Line	160103	171	10. 2
Household Cavalry	12083	—	6.55

The diseases by which this sum of sickness and mortality is made up, are thus specified in the Statistical Report:—

* On Tuberculosis, p. 370.

* Table XIX, p. 400.

TABLE III.

Diseases of the Lungs in the Troops serving in the United Kingdom during 10 years. Aggregate strength, 266,680; mean strength per annum, 26,668.

	Household Cavalry, 12,088.		Dragoon Guards and Dra- goons, 54,874.		Foot Guards, 40,120.		Infantry of the Line, 160,108.	
	Admitted.	Died.	Admitted.	Died.	Admitted.	Died.	Admitted.	Died.
Inflammation of the lungs	Not stated.	—	337	24	539	42	1897	155
Pleurisy		—	16	2	31	2	311	10
Spitting of blood		—	115	18	311	17	382	36
Consumption		76	386	307	654	479	1657	1241

Chronic catarrh		—	939	29	301	7	3375	135
Asthma		—	46	5	—	—	86	2
Difficulty of breathing		1	60	3	15	—	240	7
Breast pang		—	—	—	1	1	—	—
Total		79	8281	400	6443	555	27436	1641
Ratio per 1000 of mean strength..		6.6	152.	7.3	161.	13.8	171.	10.2

The annual ratio of deaths from pulmonary diseases per 1000 living of the civil population, in twenty-four large towns, estimated by Colonel Tulloch from the Registrar-General's Reports, appears to be—

From 20 to 40 years of age	6.3
„ 15 to 50 years of age	6.51

So that the proportion of deaths from these diseases, of which consumption forms by far the most considerable item, is very much greater among soldiers than in a town population. In the foot guards it is as 13.8 to 6.3, and in the army in the aggregate as 7.3 to 6.3.

I now proceed to compare the mortality from *phthisis*, in the British troops, with the mortality from the same disease in the male population of England and Wales, at the same periods of life, which is not done in the report.

The aggregate strength of the troops, in the years 1846-7, being 30,280, the deaths recorded from *phthisis* were 249; this gives 1 death in 121.6.

The male population of England and Wales, between the ages of fifteen and fifty, estimated to the middle of the year 1847, was 4,150,888, and the deaths from *phthisis*, 16,764; the male population from twenty to forty years of age, during the same year, numbered 2,502,233, and the deaths from *phthisis* were 11,089; * these figures give—

From 20 to 40 years of age	1 in 225.6
„ 15 to 50 years of age	1 in 247.6

So that the proportion of deaths from *phthisis* recorded in the British army, stationed at home, may be stated at about double the proportion of deaths from the same disease, in the male population of the kingdom, at the same periods of life.

In addition to this, 71 soldiers died of hæmoptysis, which, not being recorded as *phthisis*, I have omitted. This tends to show that the estimate for the army is under rather than over the truth.

It appears that the profession of a soldier, even in times of peace, is not conducive to health; and that the chief source of mortality among soldiers, as among civilians, at the age of military service, is disease of the lungs; and, moreover, that the great difference in the mortality of different troops exhibits itself especially in this class of diseases. The infantry suffer more than the cavalry; in the household cavalry, the deaths are much the same as among the civil population; but the mortality is greater in the foot guards than the aggregate mortality from all diseases, at the same periods of life, among the population generally; and this high mortality is mainly attributable to consumption. Colonel Tulloch and Dr.

Balfour regard the circumstances which, by their combination, act as causes of this mortality, to be as follows: 1. Defective barrack accommodation; 2. The great amount of night duty; 3. The deteriorating influence of a residence in large towns, giving greater facilities for, and temptation to dissipation. The high mortality in the foot guards is referred to some cause specially connected with the metropolis; since, in regiments of the line brought to London, the loss was still greater than in the guards, whom these replaced; and conversely, when the guards took the place of troops of the line abroad, the admissions and deaths in the former were considerably below their usual average. Thus, the admissions into hospital for pulmonary disease, and the deaths, were:

	Admissions per 1000 mean strength.	Deaths per 1000 mean str.
In Regiments of the Line serving in Canada	157	6.3
In the Foot Guards serving in Canada	108	6.5
In the Foot Guards serving in the United Kingdom	161	13.8

As respects barrack accommodation, the insalubrity of the sites of those in the Tower of London, and the Portman Barracks, is especially mentioned, as resulting in an increased number of fever and pulmonary cases, the two classes of diseases upon which the mortality most depends. The following is the ratio per 1,000 of mean strength admitted into hospital for diseases of the lungs, in the different barracks:

The Tower of London	176
Portman Barracks	179
Wellington Barracks	163
St. George's Barracks	185.
Detached (St. John's Wood, Kensington, Hyde Park, etc.)	139
Windsor Barracks	161
Winchester Barracks	130
Regiments of the Line in the Tower	199

The deaths are not stated, the majority being chronic cases, and the subjects of them liable to frequent removals; so that the mortality could be of very little use in determining the influence of each locality over the disease.

The returns exhibit a remarkable uniformity in the admissions into the military hospitals and deaths among the foot guards and regiments of the line, under the heads of inflammatory affections of the lungs. There is no great difference in the admissions for chronic diseases of this class; but the deaths from the latter, in the foot guards, are nearly double those in the Dragoon guards and Dragoons, and about one-third higher than in regiments of the line, as shewn in—

* Idem.

TABLE IV.

	Diseases of the Lungs. Annual ratio per 1000 of mean strength.		Inflammation of the lungs, pleurisy, acute catarrh. Annual ratio per 1000 of mean strength.		Spitting of blood, consumption, chronic catarrh, asthma, and difficult breathing. Annual ratio per 1000 of mean strength.	
	Admitted.	Died.	Admitted.	Died.	Admitted.	Died.
Dragoon Guards and Dragoons	152	7.9	124	.7	28	6.0
Infantry of the Line	171	10.2	135	1.3	36	8.9
Foot Guards	161	13.8	120	1.3	32	12.5
Household Cavalry	Not stated.	6.6	Not stated.	.2	Not stated.	6.4

Most of the deaths returned under the head "chronic catarrh" were found, on examination of the Reports, to have been really cases of consumption.

By Table III we find that the fatal termination of phthisis was not traced.

In 79 cases out of 386 Dragoons.
 " 175 cases out of 654 Foot Guards.
 " 416 cases out of 1657 The Line.

These numbers include all who survived sufficiently long to be placed on the pension list, or who partially recovered, but were subsequently taken again into hospital as new cases, and, accordingly, can by no means be regarded as instances of recovery.

An interesting part of the Report, bearing directly on the subject of tuberculosis, is that which refers to the duration of life among soldiers after having been placed on the pension list for consumption. We find that, in the force generally, among those pensioned on account of this disease, the mortality, as compared with the mortality from the same disease among those who remain in the service, is greatly diminished. It is true that the tables exhibit a very high mortality among pensioners from the foot guards, who, for several years before their discharge, had resided chiefly in the metropolis. This, however, is an exception, the mortality being one-third higher than that of the general mass of pensioners, chiefly owing to the additional prevalence of consumption, so common to these men, and so fatal during their servitude; but the duration of life generally shows a diminished mortality. Of 501 individuals among the dragoon guards and dragoons serving at home, attacked by consumption and hæmoptysis, 325, or 10 in 15½, died "during the comparatively limited period that a soldier is under hospital treatment"; the remainder not being instances of recovery, but including all who survived long enough to be placed on the pension list, or who partially recovered. Of 307 soldiers pensioned for the same disease, only 187 died in the course of sixteen years.

It has been lately discovered that this circumstance is in part attributable to fraudulent practices by personation after decease; owing to which, the true rate of mortality has been concealed by a reduction of the number of deaths below its natural standard. This has been actually effected to a considerable extent, for the purpose of drawing the pension after the decease of the individual; and since the detection of these frauds, the rate of mortality has considerably increased.

But this is by no means an adequate explanation of the whole of the discrepancy; and Col. Tulloch infers that the disabilities must have been exaggerated. He states that, making all allowance for the latitude permitted in stating the diseases for which soldiers are discharged for pension, it is impossible to avoid drawing the conclusion that many of the diseases in question have been simulated, or that the medical officers must have been much deceived as to their serious character.

In the review of my work in the *Monthly Journal*,* and in some private communications, it has been objected, that

I am inclined to place too much reliance on statistics of this nature. The Edinburgh reviewer, remarking on my chapter relating to the Causes of Tuberculosis, considers that all true research into this matter must be founded on an accurate diagnosis and a sound pathology; in which sentiment I most cordially agree, as shown by the fact, that I have devoted above one hundred pages to the Symptoms and Diagnosis, and above two hundred pages to the Special Pathological Anatomy of the disease. But he further states, that such elements form no essential part of modern statistics, which accordingly merit no confidence. I believe, notwithstanding the different conclusions arrived at by Mr Phillips and myself, to which the reviewer refers, and which I will notice again in a subsequent paper, that this is too sweeping a condemnation of the medical statistics in question. Throughout my work I have dwelt on and regretted the imperfections of this branch of science, and have inculcated and endeavoured to practise the utmost caution in forming deductions; but, at the same time, I should regret exceedingly an error in the opposite direction causing their use to be neglected. As respects such a disease as phthisis, I do not believe that the reports furnished to the Registrar General and the War Office are so utterly worthless. The returns are uniformly made by qualified medical practitioners. I know very well that errors of diagnosis are very frequent; but these are errors committed during the lifetime of the patient, and generally in the earlier period of the disease. It is not probable that medical practitioners can very frequently make erroneous returns, after this disease has run its course and terminated in death. On my own experience, I affirm that, whether in public or in private practice, I scarcely remember a case where phthisis has been predicated, by a medical practitioner, before a *post mortem* examination, and found to be absent. It is true that tubercles are more frequently found, unexpectedly, where death has been produced by other diseases; and this leads to the remark, that sources of error which affect the total range and operate at one time as well as another, however this may render caution and qualification necessary, do not vitiate the statistics for comparative inductions, particularly when those statistics are on a large scale. Thus, in the present paper, I have shown from Colonel Tulloch's and the Registrar General's reports, that death from phthisis in the foot guards was about twice as frequent as in the male civil population, at the periods of life for military service. Were I to adopt the formula two to one, and reason therefrom, I should commit a very grave mistake. In the first place, the comparison is made between a period of about thirty years in the one case, and one year in the other; although the numbers are very much greater in the latter than in the former period. In the next place, I am assured of the deficiency of facts, especially those relating to the complications of disease, and the occasional errors in the data upon which both the Registrar General's and the Military Superintendent's results are founded. Nevertheless, it can scarcely be denied that it is a broad and highly important statistical fact, that death occurs much more frequently from phthisis in the Foot Guards serving in London, than in the civil population; a fact, respecting which we might have entertained conjectures, but of which we should have had no knowledge, had it

* July 1853.

not been for statistics. Other equally apposite instances might be drawn from the above tables, and the legitimate deductions which they furnish; and I shall avail myself of some of these in elucidation of certain points in a future paper. But this one is, I think, sufficient to obtain the admission that these statistics, although imperfect, have a positive value; and I may add, that they will be found to possess a highly important relative value, when employed to counteract hasty generalisation, from statistical data, more accurate in themselves, but upon too limited a scale.

Adverting, then, to another statistical fact, the apparent increased duration of life among soldiers discharged the service for consumption, as compared with the duration of life among those remaining in the service, and the explanations of that fact by Colonel Tulloch and Dr. Balfour, referring it to fraud, malingering, and errors of diagnosis,—is not another, and a more satisfactory explanation admissible? Is it not possible that some of these men, actually affected with phthisis, recover after their discharge from military service and military regimen; or, that the disease is for a longer or shorter time arrested? Precisely analogous circumstances occur in relation to prisoners and prison discipline. Dr. Baly found the mortality from consumption during one year, in the Millbank Penitentiary, nearly four times more than the mortality from the same disease in the metropolis; and among a population of 76,535 prisoners, in the prisons and penitentiaries of various countries, he found the deaths from phthisis 1 in 118·7 of the whole number living, and 1 in 2·9 of the deaths.* But Dr. Baly states that "Prisoners who are even in an advanced stage of consumption, and who in the infirmary were gradually and rapidly getting worse, on release from confinement immediately improved." The true causes of this improvement after release from imprisonment, or discharge from military service, are as interesting and important a practical question, as the causes of the production of tuberculosis, and their *modus operandi* during imprisonment.

The statistical information before us, as to the present prevalence of phthisis both in the civil and in the military populations of this kingdom, leads me to conclude this paper with another remark, which must have occurred to many readers. Considering the high opinions for some time past entertained of the curative powers of cod liver oil, which has now been several years in general use, it must be admitted that the ultimate results are by no means encouraging. The comparison between the years 1851 and 1852, exhibits but a very trifling amelioration. Nor is there reason to be much better satisfied with these gross results, when we trace the disease back chronologically to a period previous to the introduction of the remedy; for, although, in 1841, the proportion of deaths to the population, from the four forms in the aggregate, and from phthisis in particular, was considerably greater, yet the amelioration observable cannot be attributed to this remedy alone, which has been in general use only during the last few years; and in 1850, the fatality was proportionately less than during either of the two subsequent years. So, also, we find, by comparing the statistics in Colonel Tulloch's recent and former reports, that during the last ten years, no decided amelioration appears, either in the frequency or the fatality of this disease. Our disappointment at this result is the greater, inasmuch as the statistical records of Philadelphia indicate a very great diminution of deaths from phthisis during the years 1850 and 1851, which Dr. Wood, in his work on the Practice of Physic, recently published, has attributed to the general use of the oil. For my own part, I am not in the slightest degree shaken in my opinion of the value of the oil, notwithstanding its manifest general failure as regards a cure. As stated more fully in my work, I have always regarded it as an auxiliary to a rational system of therapeutical indications; and I still fear, that we are deprived of the full measure of its beneficial

agency, by its employment, too frequently, on the empirical principle.

The statistics of tuberculosis in the troops serving in the Mediterranean and British America, during the last ten years, will form the subject of a future communication.

3, Norfolk Crescent, Hyde Park, Sept. 1853.

ACCOUNT OF THE YELLOW FEVER OF ANTIGUA, AS IT PREVAILED IN 1853.

By THOMAS NICHOLSON, M.D.

[The following paper was received by us subsequent to the publication of Dr. NICHOLSON's paper, at p. 807 of our number for September 16th. EDITOR.]

YELLOW FEVER broke out in Antigua on the 15th of May, 1853,* in the person of a delicate female, a native of Scotland, who had been only eighteen months or two years in the island. This case was reported to me by an express from my son, when I was at St. Kitt's, whither I had gone for change of air, having suffered for some months from a severe attack of acute rheumatism. No other case occurred for several days; but when I arrived, on June 3rd, I learnt that my son had two other cases on his list; one, a young Scotchman, who resided not many yards from the house in which the first case occurred; the other, an army surgeon, living in another part of the city. Both these proved fatal on the fifth day, with black vomit. Cases were now added daily to the list till the end of July, our last case having proved fatal on the 31st of that month.

The following table contains an abstract of all the cases which I attended myself, or with my son, exclusive of those I saw in consultation with other medical men:—

Race.		Recovered.	Died.	Total.
Europeans	Adults	23	9	32
White Creoles	Adults	3	0	3
"	Children	0	2	2
Mixed race	Adults	0	0	0
"	Children	5	1	6
American		1	0	1
Portuguese		2	1	3
		40	13	53

The type of this epidemic, in all cases that came under my observation, was certainly that of the *ardent* form. I did not meet with a single case of the *apyretic* or *congestive* type, such as I have witnessed in former epidemics. The patient was most frequently seized in the morning. No decided rigor was observed, but he awoke with a feeling of having slept heavily, as if from a narcotic. This was immediately followed by intense headache and pain in the back; the vessels of the conjunctiva became injected and red; the force and velocity of the pulse great; and the heat of the surface pungent. At this period, the tongue presented an unusual appearance. About the third day, the febrile heat subsided; the cheeks, which had been of a florid red colour, assumed a darker hue; the lips were red, and the gums spongy and very vascular; the hands and nails became livid, and, when pressed upon, it was long before the blood returned to the cutaneous vessels. By-and-bye, a yellow tinge was perceptible on the conjunctiva, and on each side of the nose, which spread gradually over the neck and chest. Hemorrhage from the nose and mouth now took place; flatulency was very distressing; and the vomiting, which was distressing from the first, now became more urgent, and, in the fatal cases, the matter ejected was mixed with dark flakes, like the lees of port wine, which gradually became blacker and more copious till death closed the scene. In those cases which terminated favourably, the discharges from the bowels were copious, and of the darkest sap-green; and the urine was abundant, and of a good colour. In fatal cases, the motions had not the

* Medico-Chirurgical Transactions, vol. x.

† On Tuberculosis, p. 483.

* May is usually the hottest month in the year.

alightest tinge of green or yellow; and they exhaled an offensive odour like putrid albumen. In those cases, the urine was frequently suppressed, and symptoms of *uræmia* were more or less apparent.

None of the cases in my own practice presented unequivocal marks of *petechiæ*; but a military officer, under the care of Dr. Furlonge, was spotted like a leopard from head to foot: even the mucous membrane of the mouth exhibited the same symptoms of extravasation.

Death occurred most frequently on the fifth day: one died on the fourth day, two on the sixth, and one on the seventh day. In those cases in which the urinary secretion was not suspended, death took place by *asthenia*; the patient retaining his intellect till the last. When *uræmia* existed, convulsions and coma preceded death.

From a variety of causes, no *post mortem* examinations were made.

TREATMENT. When I arrived, I found the lancet had not been used in any case; but purgatives, and five grain doses of quinine, frequently repeated, with the usual auxiliaries, were chiefly confided in. The quinine so administered appeared to me to be decidedly injurious, and it was abandoned.

In simple cases, where there was no symptom of local congestion or inflammation, purgatives of calomel, colocyath, and jalap, saline refrigerants, and effervescing draughts, formed the chief medicinal treatment. In more severe cases, five grains of calomel were interposed every two hours. The cold douche was always most agreeable to the patient, and was constantly had recourse to in the first stage. When the headache continued beyond the second day, blisters were applied to the neck or forehead with good effect.

In all cases in which at my first visit there were symptoms of cerebral or hepatic congestion, or when the force of the circulation was so great as to threaten destruction to the capillary system, I had recourse to blood-letting; and, if we may judge of the propriety of the operation by the rules laid down by Dr. Marshall Hall, we must decide in its favour, although it did not always cure the disease. The loss of blood was well borne in every case. In one patient only was syncope induced, after the loss of twenty-four ounces, and he rapidly recovered. In all the other cases a much larger quantity of blood was drawn, whilst the patient was in the sitting posture, and syncope did not occur. The effect produced was vomiting, copious perspiration, bleaching of the eyes, and relief of the headache. When permanent reduction of the pulse followed these effects, the case invariably did well; but when the velocity of the pulse continued, the case proved a bad one, and, in my opinion, would have resisted every kind of treatment.

To prove that blood-letting did not do harm, I would mention that it was had recourse to only in the worst cases, and yet not one of these died before the fifth day, whilst two of them lived till the sixth, and one till the seventh day. Of twelve cases in which the lancet was used, six recovered, and six died. In no case was the operation repeated; and it is a question whether the advocates of this practice would not have deemed it right to repeat the operation at a short interval, when the pulse continued quick. But the prejudice which has been excited by modern writers against large detractions of blood in fevers deterred me.

Having lost in succession four cases in which blood-letting was performed, either by myself or in my presence, with all the immediate effects which follow a successful operation, I considered that I was then bound conscientiously to try the empirical or abortive treatment, with large doses of quinine and calomel, as recommended by Dr. Blair of Demarara. The first case that occurred for this trial was that of a young Scotchman, who had recently come to the island. The second dose produced great congestion of the brain, and a stupor from which he could scarcely be roused, and he died on the fourth day. Nevertheless, our next case was treated in the same way, with twenty grains of calomel and twenty-four grains of quinine. Great drowsiness was the immediate result, and we were deterred from continuing the

practice. We resumed our former mode of treatment, and the patient recovered.

It is unnecessary to enter upon the treatment that was pursued after hæmorrhages and black vomit occurred; for I have no confidence then in any medicinal astringent, or in anything but the most diligent exhibition of diffusible stimulants. Patients have sometimes recovered after all hope was abandoned. This was the case with two seamen, who were landed here from a ship bound from St. Thomas to Barbadoes. They were in the last stage of the disease, with hæmorrhages from the nose, mouth, and anus, and black vomit, when admitted into the Infirmary. Sulphate of alum with quinine, tannic acid, and acetate of lead, were successively prescribed; but I discovered that they took nothing freely except their wine.

PERISCOPIC REVIEW.

SURGERY.

SUCCESSFUL CASES OF OPERATION ON THE BONES OF THE FACE.

In the periodicals of the current year, we have met with accounts of two remarkable successful operations on the bones of the face.

The first case occurred in the practice of Dr. B. LANGENBECK of Berlin. It is reported in the *Deutsche Klinik* for 30th April, 1853.

CASE I. MEDULLARY CARCINOMA OF THE UPPER JAW; EXCISION OF THE WHOLE OF THE LEFT UPPER JAW BONE, AND NEARLY ALL THE RIGHT; ALSO OF THE LEFT NASAL BONE, AND OF THE ETHMOID BONE: RECOVERY. A. J., aged 19, an unmarried female, was admitted into hospital on February 17th. With the exception of repeated attacks of intermittent fever, the patient had enjoyed good health. No hereditary predisposition to carcinoma had appeared in her family. In the summer of 1852, she felt a violent pain in the teeth and ear on the left side, and perceived that the left nostril was less permeable to air than usual. At Michaelmas of the same year, she was seized with pains in the forehead; and some time afterwards, a swelling was noticed in the left nostril. This became conspicuous under the skin of the cheek, extending outwards from the ala nasi; and from this time it rapidly increased in size. In the right half of the nose, a similar but much smaller tumour appeared, some weeks before the admission of the patient into hospital; this had been preceded by obstruction of the nostril, and by pain in the teeth and right upper maxillary bone. At the end of January, the tumour arrived at the surface by a perforation of the upper lip, in a direction downwards and outwards from the left nostril.

On examination, there was found in the region of the left superior maxillary bone a tumour of about the size of a moderately large orange. It was covered at the centre by a red skin, and presented, at the part above referred to, a perforation in the upper lip; while it was also visible through the expanded left nostril. In the neighbourhood of the tumour, which was scarcely sensible to pressure, there was an oedematous swelling of the face, painful to the touch, and most conspicuous at the inner angle of the left eye. On the right side there was a smaller swelling, more easily felt than seen; it seemed to occupy a large part of the nostril, so that the finger could be introduced only with difficulty. On this side, there was oedematous swelling of the inner angle of the eye and the lower eyelid; but nothing abnormal was perceived in the nasal bones. On examining the mouth, the whole of the left side of the upper lip, beyond the middle line, as far as the right ala nasi, was occupied by the tumour, which was pressed on by the incisor and first molar teeth in the left upper jaw-bone on the inside, and by the skin of the upper lip in front. A part of the tumour, in the neighbourhood of the teeth, was covered with ulcerative exudation. Almost the entire extent of the hard palate, especially at its anterior part, was a very irregular projection of the mucous membrane, caused by pressure from above downwards of the tumour, which flattened the arch of the palate. In it were several ulcerated spots, into which a probe could be passed for some distance, especially on the left side. On this side the tumour extended as far back as the molar teeth; and four weeks

previously, the three molars had been pushed out by it; the second bicuspid, which still remained, was loose. On the right side, the swelling was about three lines distant from the alveolar border. The teeth, both those which had been removed and those which remained, were in excellent preservation; the velum palati and soft parts were healthy. The exhalation from the tumour was very fetid, and could only be somewhat improved by the use of chlorine water. The general health was not greatly impaired; digestion was good; the pulse was 116. The patient had pain only in the teeth, by which she had been deprived of sleep during some nights. She did not observe that she had lately lost flesh to any remarkable extent.

The diagnosis was easy, as no other than a carcinomatous tumour could have produced the phenomena presented. The prognosis also admitted of no doubt; for it was plain that, if the tumour were left to itself, its rapid progress would soon destroy the patient. An operation was therefore performed on February 22nd, by Dr. Langenbeck.

The patient was placed on a somewhat elevated seat. Chloroform was administered, and she remained under its influence during the first part of the operation. An incision was made on the left side through the cheek, from above the lachrymal sac, perpendicularly downwards, passing close to the ala nasi, as far as the upper lip near the angle of the mouth. From the upper end of this incision, a horizontal one was carried outwards, parallel with the edge of the orbit, as far as the zygoma. The flap was turned back, and a portion of the tumour brought into sight. The bulb of the eye was now separated from the orbital part of the upper jaw-bone; and the frontal and temporal processes were divided by a saw and forceps. On the right side, an incision was carried obliquely from the malar bone to the angle of the mouth; and the whole of the middle part of the face, surrounding the nose, was separated and pushed upwards. The nasal process of the left upper maxillary bone was now divided with bone forceps; this bone, which was entirely involved in the disease, along with the left nasal bone, was removed, with a part of the bone on right side. By removal of a diseased part of the wall of the left frontal sinus, this cavity was laid open; and the right upper jaw-bone was removed by sawing it obliquely downwards and outwards from the upper part of the foramen lacerum to below the infra-orbital foramen. The vomer was divided with bone-forceps; and, by powerful pressure downwards, the upper jaw was removed from its connection with the pterygoid processes: the soft palate was separated by an incision close to its attached borders. After the removal of the principal part of the tumour, the remaining parts were removed with forceps, so that the greater part of the ethmoid bone as far as the cribriform plate was taken away. Some portions which still remained, and which could not be reached without great difficulty, were touched with the actual cautery. Carcinomatous masses were removed from the inner surface of the skin, and from the nose and upper lip. The hæmorrhage was not considerable, all the arteries which were wounded at the commencement of the operation having retracted and ceased to bleed. Dossils, with threads fastened to them, were placed on the surface of the wound; the threads hanging out at the angle of the mouth, and through the nostrils. The incisions in the face were then united by knotted and twisted sutures.

Chloroform was used at the commencement of the operation, but was not repeated when its effect passed off, on account of the danger of the entrance of blood into the air-passages. The patient bore the operation very courageously: she fainted once, but only for a short time. After the operation, she drank some wine: it was administered partly by a teaspoon, and partly through a tube. Cold lotions were applied, and a quarter of a grain of acetate of morphia was given. In the evening, the pulse was 120, and stronger than immediately after the operation.

The tumour was found on examination to be medullary carcinoma. It occupied nearly the entire upper maxillary region, and produced a strong arching forward of the canine fossa on the left side, but less on the right. Besides projecting through the hard palate into the mouth, it filled all the other neighbouring cavities, as the nostrils, the maxillary sinuses, and the left side of the frontal sinus, so that it extended as far as the base of the skull. The adjoining bones were perforated by it in some parts, but were otherwise healthy. The tumour was throughout of a white medullary appearance, with spots of effused blood in some parts. On microscopic examination, it was found to consist entirely of roundish cells with several nuclei; no fibres nor spindle-shaped cells were anywhere apparent.

The subsequent daily reports show a steadily favourable pro-

gress of the case. On March 9th the patient sat up: on the 26th, the whole of the wounds in the face had cicatrised. On April 19th, the patient was dismissed. The cicatrices in face had become small; there was slight œdema of the right lower eyelid, and of both left eyelids. The nose was somewhat sunken, being deprived of its osseous support, and had at the point a slight inclination to the left. The cheeks had regained a fair amount of their original roundness. The opening of the mouth, which had been diminished by the removal of a portion of the upper lip, could only be closed by pushing up the lower lip; and not perfectly then, as the upper lip and cheeks were almost entirely deprived of motion, through division of the twigs of the facial nerve. In the cavity of the mouth, the greatest part of what had been removed during the operation was replaced by new deposit, so that the soft palate, excepting a small spot in the centre, was attached nearly as firmly as before. The most perfect reparation had taken place on the left side; the least in the centre and on the nasal bones. The newly formed masses were partly covered with mucous membrane, partly with purulent exudation. Speech had been almost unintelligible soon after the operation; but had become as distinct as could be expected. Deglutition was perfect; but the patient was naturally as yet unable to chew anything. The general health was good; and the catamenia had appeared at the proper time, and continued for the usual period. Whether the cure will be permanent, can only be shown by time.

The second case is given in the *Union Médicale* for Aug. 11.

CASE II. IVORY EXOSTOSIS OF THE ETHMOID BONE, OCCUPYING THE ENTIRE RIGHT SIDE OF THAT BONE: COMPLETE EXTIRPATION: RAPID RECOVERY, WITH PERFECT PRESERVATION OF THE FUNCTIONS AND MOVEMENTS OF THE EYE. M. MAISONNEUVE presented, at a meeting of the Academy of Sciences, a young man from whom he had three months previously removed the right half of the ethmoid bone, on account of exostosis.

T. J., aged 22, a workman, of robust constitution, in the early part of March 1853, began to feel a kind of weight and dull pain in the orbital region, and the right eye became more projecting than the other. He had first paid little attention to this: but soon the orbital pain became intense, and his eye felt as if squeezed in a vice. The organ began to turn outwards, and to project from the orbit, pushing the eyelids forward. A medical man who was consulted recognised the presence of exophthalmia, caused by a hard tumour towards the deep and interior part of the orbit: and he advised the patient to place himself under the care of M. Maisonneuve.

On July 5th, M. Maisonneuve saw the patient for the first time. The right eye was completely pushed out of the orbit, towards the temple. The eyelids covered the eye very imperfectly: and the conjunctiva was inflamed. The tears pursued their regular course; and vision was not entirely lost. At the internal angle of the eye was felt the rounded point of a tumour, evidently deeply seated, whose presence was ascertained by depressing the soft parts. The tumour had an osseous hardness; it was scarcely sensible to pressure; but it was the seat of dull continued pain, which fatigued the patient much, and prevented sleep. The corresponding nostril was free. M. Maisonneuve diagnosed the existence of exostosis of the interior wall of the orbit—probably ivory exostosis.

The patient had never received a blow on the eye; he had never had syphilis, nor cutaneous diseases, nor scrofula. Before attempting surgical interference, M. Maisonneuve determined to try the effect of iodine. Half a drachm of iodide of potassium was given in twenty-four hours. This was continued for a fortnight, without effect; and, as the tumour increased in size and the pain continued, an operation was determined on.

On July 14th, the patient having been chloroformed, a semi-circular incision was made along the internal part of the circumference of the orbit, commencing above the eyebrow. The soft parts were dissected as far as the bones: the periosteum comprised in the flap carried with it the orbicularis muscle and the pulley of the superior oblique. This dissection disclosed the anterior part of the tumour, and a portion of its internal surface. At this stage, three or four arterial twigs were ligatured: and now commenced the difficult part of the operation.

The tumour, encrusted by the inner wall of the orbit, filled more than two thirds of that cavity. Its base was not narrowed, and seemed to be continuous with the superior and inferior, as well as with the interior walls of the orbit. Its posterior extremity was too deeply seated to allow its limit to be ascertained. The anterior part alone offered a mammillated projection, by which hold could be taken of the tumour. M. Maisonneuve first made several attempts to use the saws of Charrière, Martin,

etc.; but the narrowing of the cavity prevented their employment. Liston's forceps were then tried; but these made no impression on the tumour, and two pairs were broken in the attempt.

The surgeon then tried to make impression on the tumour with a hammer and chisel. It resisted this treatment also; but one of the projections, of the size of a nut, was detached after great effort, and thrown to a distance. This circumstance decided the success of the operation. Behind the part thus removed, the tumour presented a neck or groove where the osseous tissue was less dense. The chisel, forcibly driven by the hammer, penetrated to a certain depth; and a very slight degree of mobility was immediately perceived in the tumour.

It now seemed as if the operation would be easily completed: but new difficulties arose. The tumour formed, in the nasal fosse, a projection almost similar to that in the orbit; and these two portions were in a manner strangulated by a bony ring formed above by the frontal, below and in front by the superior maxillary bone and its ascending process. It was only after long and laborious efforts, with levers of all kinds, forceps, etc., that the tumour was at last removed entire.

On introducing his finger into the deep cavity left by the removal of the tumour, M. Maisonneuve discovered that its interior was perfectly smooth, and lined with a sort of tomentous membrane. There was no apparent communication with the maxillary sinus nor with the nasal fosse.

During this difficult operation, the eye had not been injured, and the bones in the vicinity of the tumour had been carefully guarded. M. Maisonneuve therefore replaced the eye in the orbit, and united the edges of the wound by the twisted suture. The operation continued an hour and a half.

No inflammatory symptoms arose either in the brain, or even in the deeply seated structures of the face, or in the eye. The eye, when replaced, almost immediately resumed its functions: its movements all remained perfect. The wound healed by the first intention; and the traumatic fever was scarcely sensible.

The tumour was found to be an ivory exostosis; it resembled in form the ethmoid bone. Its antero-posterior diameter was five *centimètres* (nearly two inches); and its transverse and vertical diameters each four *centimètres* (an inch and a half). Its inner surface was smooth and regular; the outer was curved and covered with projections. The upper surface presented, in front, a deep excavation, which showed traces of a rupture; at this point the tumour had been united with the frontal bone to the extent of two *centimètres* (seven-tenths of an inch). The anterior surface was divided vertically by a groove, whose edges embraced the ascending process of the superior maxillary bone; the posterior part represented a round edge, the upper tubercle of which corresponded to the optic foramen. The tumour weighed twenty-eight *grammes* (432 grains).

On August 9th, it was difficult to determine on which side the operation had been performed. The cicatrix was imperceptible; the eye was perfectly similar to the other; it executed all the movements of elevation, depression, adduction, abduction, and rotation. The eyelids retained their mobility, and the lachrymal apparatus properly performed its functions.

REMOVAL BY TRACHEOTOMY OF A GRAIN OF CORN LODGED AT THE BIFURCATION OF THE BRONCHI.

Dr. B. S. G. PEACHY, in his "Clinical Reports of the College Infirmary of Richmond (Virginia, U.S.)," published in the *Virginia Medical and Surgical Journal* for April 1853, describes the following case, which occurred under Dr. Johnson.

R. S., of Powhatan county, Virginia, aged 8, while running with a grain of corn in his mouth, got it jostled into the larynx, whence it fell into the trachea, and finally lodged at the bifurcation of the bronchi. At this point it remained for ten days before the patient was brought to the infirmary. At the time of entrance he appeared much distressed and uneasy, felt sore all along the trachea, and disposed "to cough out something in his throat". When the patient was directed to cough, the foreign body was distinctly felt to strike against the sides of the larynx and trachea. It was determined to place the patient under the influence of chloroform, and to perform tracheotomy. An incision was made in the median line; the fascia was cautiously dissected from the trachea before incising the latter, inasmuch as an incision made directly through both would have been attended with escape of air, which, finding its way into the cut areolar tissue would have given rise to emphysema, an occurrence zealously to be guarded against. The slight hemorrhage having been arrested, the trachea was next incised to the extent of some five or six rings. The irritation occasioned by the entrance of

air through this opening caused violent heaving of the chest. The face at times was perfectly livid. This lasted several minutes, when comparative quiet seemed to be restored. As soon as blunt hooks were introduced to expand the wound and allow extrication of the foreign body, the spasmodic efforts would recur and prevent their insertion. Having once succeeded, however in dilating the incision, a violent fit of coughing expelled the grain of corn, and all irritation at once subsided. The edges of incision were brought together by Liston's adhesive strips, and cold water was applied. With the exception of considerable fever the night subsequent to the operation, and some excitement and heat of skin for a day or two after, the patient suffered not, but recovered entirely, and was discharged in less than a fortnight.

DIAGNOSIS OF FRACTURE OF THE BASE OF THE SKULL.

In the *Annales de la Société Médico-Chirurgicale de Bruges*, as quoted in the *Gazette Médicale* for August 6th, M. GIGOT expresses his opinion that the escape of blood by the ear and subconjunctival ecchymosis are not always pathognomonic of fracture of the base of the skull, though they are nevertheless of great importance in the diagnosis of injuries of this organ. He has noticed a case where a fall on the head was followed by deep bluish red ecchymosis in the subconjunctival tissue of the inner half of the left eye, and by the discharge, during two days, of a rather large quantity of serous transparent fluid through the right ear. There were at first somnolence and general semi-paralysis; there was also a swelling, of the size of a nut, an inch below and to the right of the occipital protuberance. In spite of the unfavourable symptoms, the patient began to recover in five days, and got completely well.

M. Gigot explains the escape of watery fluid, by the laceration of the arachnoid cul-de-sac which accompanies the auditory nerve in the internal auditory meatus. The infiltration of the subconjunctival cellular tissue was produced probably by more or less extensive detachment of the bones of the orbital arch. The blood would then traverse by imbibition the fibrous layer, to be effused into the loose cellular tissue which surrounds the globe of the eye, and is connected with the subconjunctival cellular tissue; and thus in time it would arrive at the cellular tissue of the eyelids.

ARBUTUS UNEDO IN BLENNORRAGIA.

In the *Union Médicale* for August 2nd, Dr. VENOT of Bordeaux states that he has employed the *arbutus unedo* in cases of blennorrhagia and blennorrhœa. Its property depends on a highly astringent principle. He uses it in the following forms:

Injection. Take of aqueous extract of *arbutus unedo*, 30 parts;

Distilled water, 100 parts.

Syrup. Take of aqueous extract of *arbutus unedo*, 25 parts; Cold distilled water, 125 parts.

Dissolve, filter, and mix with simple syrup, reduced a fourth part by boiling, 500 parts.

Mixture. Take of syrup of *arbutus*, syrup of Tolu, each 30 parts;

Distilled pine-water, 100 parts.

Mix: to be taken in spoonful doses.

Pills. Take of extract of *arbutus unedo*, extract of *rhatany*, each 75 grains.

Mix and divide into twenty-five pills; two to be taken morning and evening.

Dr. Venot states that this medicine surpasses *rhatany*, and is an admirable adjunct to *cubebs* and *copaiba*.

FRACTURE OF THE TROCHLEA OF THE HUMERUS.

In the *Archives Générales de Médecine*, as quoted in the *Gazette Médicale* for April 16th, M. LATOIGN describes a variety of fracture of the trochlea of the humerus. The following are its diagnostic signs.

The fracture of the trochlea may be produced by a fall on the palm of the hand: it leaves the passive movements of the fore arm entire: extension of the limb is accompanied by inclination inwards of the forearm on the arm at a very obtuse angle, the summit of which corresponds to the epitrochlea: in resisting this, there is an abnormal amount of transverse mobility, and distinct crepitation: the ulna is not displaced backwards or inwards: the olecranon is immoveable on the ulna: the two condyles of the humerus are immoveable, either on the bone, or on each other.

REPORTS OF SOCIETIES.

TWENTY-THIRD ANNUAL MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

[Held at Hull, September 7th to 15th, 1853.]

WEDNESDAY, SEPTEMBER 15.

REPORT OF COUNCIL.

The General Committee assembled in the Library of the Infirmary, at 1 o'clock, when Professor PHILLIPS, the Assistant General Secretary, read the Report of the Council. This consisted of an account of their proceedings with regard to certain scientific subjects which had been referred to them at the last meeting of the association at Belfast, in 1852.

TREASURER'S ACCOUNT.

Mr. NINNIS read the abstract of the Treasurer's account; from which it appeared that the statement for the year was—

Receipts - - - -	£ 1715	1	0
Payments - - - -	1487	1	7
Balance at the Bankers' and in Treasurer's hands	227	10	11

FIRST GENERAL MEETING.

The first general meeting was held in the Mechanics' Institution, at 8 P.M. Colonel SABINE, the retiring President, took the Chair, and forthwith resigned it to Mr. HOPKINS, the President-elect, who delivered an inaugural address. He reviewed the progress which had been made during the last few years, in astronomy, terrestrial magnetism, the nature of heat, and geology. We are compelled to omit any abstract of Mr. Hopkins' luminous remarks on these subjects; but we must transfer to our pages some excellent observations on the objects of the Association.

"There are probably few amongst us of whom the inquiry has not been made—after any one of our meetings—whether any striking discovery had been brought forward?—and most of us will also probably have remarked that an answer in the negative has frequently produced something like a feeling of disappointment in the inquirer. But such a feeling can arise only from a misapprehension of what I conceive to be the real and legitimate objects of the British Association. Great discoveries do not require associations to proclaim them to the world. They proclaim themselves. We do not meet to receive their announcement, or to make a display of our scientific labours in the eyes of the world, or to compliment each other on the success that we may have met with. Outward display belongs not to the proceedings, and the expression of mutual compliment belongs not to the language, of earnest minded men. We meet, gentlemen, if I comprehend our purpose rightly, to assist and encourage each other in the performance of the laborious daily tasks of detailed scientific investigation. A great thought may possibly arise almost instantaneously in the mind,—and the intuition of genius may almost as immediately recognise its importance, and partly foresee its consequences. Individual labour may also do much in establishing the truth of a new principle of theory; but what an amount of labour may its multifarious applications involve! Nearly two centuries have not sufficed to work out all the consequences of the principle of gravitation. Every theory, as it becomes more and more perfectly worked out, embraces a greater number of phenomena, and requires a greater number of labourers for its complete development. Thus it is that, when science has arrived at a certain stage, combination and cooperation become so essential for its further progress. Each scientific society effects this object in a greater or less degree; but much of its influence may be of a local character, and it is usually restricted by a limited range of its objects. Up to a certain point, no means are probably so effective for the promotion of science as those particular societies which devote themselves to one particular branch of science; but as each science expands, it comes into nearer relations with other sciences, and a period must arrive in this general and progressive advance which must render the cooperation of the cultivators of different branches of science almost as essential to our general progress, as the combination of those who cultivate the same branch was essential to the progress of each particular science in its earlier stages. It is the feeling of the necessity of combination and of facility of intercourse among men of science that has given rise to a strong wish that the scientific memoirs of different societies should be rendered, by some

general plan, more easily and generally accessible than they are at present:—a subject which I would press on your consideration. It is by promoting this combination, that the British Association has been able to exert so beneficial an influence,—by bringing scientific men together, and thus placing, as it were, in juxtaposition every society in the country. But how has this influence been exercised? Not assuredly in the promotion of vague theories and speculative novelties; but in the encouragement of the hard daily toil of scientific research, and by the work which it has caused to be done, whether by its influence over its individual members or on the Government of the country. Regarding our Association, gentlemen, in this point of view, I can only see an increased demand for its labours, and not a termination of them, in the future progress of science. The wider the spread of science, the wider will be the sphere of its usefulness."

Mr. Hopkins, in concluding his address, after referring to the importance of science as a means of supplying the present wants of men, proceeded to say that—

"If we would view science under its noblest aspects, we must regard it with reference to man, not merely as a creature of physical wants, but as a being of intellectual and moral endowments, fitting him to discover and comprehend some part at least of the laws which govern the material universe, to admire the harmony which pervades it, and to love and worship its Creator. It is for science, as it leads to this contemplation of nature, and to a stronger sense of the beauties which God has spread around us, that I would claim your deeper reverence. Let us cultivate science for its own sake, as well as for the practical advantages which flow from it. Nor let it be feared lest this cultivation of what I may term contemplative science, if prosecuted in a really philosophic spirit, should inspire us with vain and presumptuous thoughts, or disqualify us for the due appreciation of moral evidence on the most sacred and important subjects which can occupy our minds. There is far more vanity and presumption in ignorance than in sound knowledge; and the spirit of true philosophy, be it ever remembered, is a patient, a modest, and a humble spirit."

THURSDAY, SEPTEMBER 8.

SECTIONAL MEETINGS.

The Committee of Sections met at 10 o'clock, and the Sections at 11 o'clock.

[We shall give the reports of the Sectional Meetings in a collected form in our next number.]

A SOIRÉE

was held in the Music Hall in the evening, when about 650 persons were present. The Hall was tastefully decorated, and specimens and objects of interest were exhibited.

FRIDAY, SEPTEMBER 9.—SATURDAY, SEPTEMBER 10.

SECTIONAL MEETINGS

were held on these days.

MONDAY, SEPTEMBER 12.

PLACE OF MEETING IN 1854.

Invitations for the next year's meeting were received from Liverpool, Glasgow, Dublin, Leeds, Brighton, and Gloucester.

J. HEYWOOD, Esq., M.P., moved, and Mr. SMITH, of Jordan Hill, seconded, that the meeting in 1854 be held at Liverpool. This motion was carried.

ELECTION OF OFFICERS.

The following officers were elected:—

PRESIDENT-ELECT: Lord Hartowby. VICE-PRESIDENTS: Lord Wrottesley; Sir P. M. de Grey Egerton, Bart.; Dr. Whewell; Professor Owen; W. Lassell, Esq.; and J. B. Yates, Esq. LOCAL SECRETARIES: Dr. Dickinson, and Dr. D. P. Thomson. LOCAL TREASURER: Mr. R. McAndrew. SECRETARY: Colonel Sabine. ASSISTANT GENERAL SECRETARY: Professor Phillips. COUNCIL: Dr. Walker-Arnott; Sir H. De la Beche; C. C. Babington; Prof. Bell; Prof. Daubeny; Prof. E. Forbes; Prof. Graham; J. P. Gassiot; W. R. Grove; R. Hutton; L. Horner; J. Heywood, M.P.; Sir C. Lemon; Dr. Miller; Dr. Lankester; Prof. Powell; Sir R. Madden; H. E. Strickland; Prof. Stokes; and the Bishop of Oxford.

TUESDAY, SEPTEMBER 13.

MEDICAL BREAKFAST.

On Tuesday morning, the medical visitors of the British Association, by invitation of the resident medical officers of Hull, sat down to a sumptuous breakfast. Amongst the strangers present, were Dr. Balfour (Grimsby), Dr. Balfour, Dr. Neil Arnott, and Dr. Balfour.

Dr. Latham, Dr. Lankester, Dr. Burgess, Dr. Daubeny, Dr. W. Arnott, Dr. Helmholtz, Dr. Barbridge, J. Hegg, Esq., J. P. Bell, Esq., R. J. Bell, Esq. The following resident medical gentlemen were also present—Dr. Horner, Dr. Sandwith, Dr. Cooper, Dr. Daly, Dr. Bell, Dr. Archibald, Dr. King, F. Huntingdon, Esq., R. Hardey, Esq., J. Dossor, Esq., J. Lowther, Esq., J. H. Gibson, Esq., H. Munroe, Esq., J. H. Locking, Esq., C. Beckett, Esq., R. Craven, Esq., E. Twining, Esq., R. L. Sleight, Esq., W. Hay, Esq., E. Reckitt, Esq., H. Lee, Esq., W. Hodgson, Esq., T. Atkinson, Esq., T. T. Lambert, Esq., J. Wilson, Esq. Dr. Horner occupied the chair, and H. Munroe, Esq., the vice-chair.

The president, Dr. HORNER, spoke in eulogistic terms of the high honour which the medical men of Hull felt in having the privilege of entertaining the medical members of the British Association. He was also proud to speak of the good feeling and unanimity of sentiment which pervaded the medical profession here; and particularly adverted to the cause of that existing friendship, as being derived from the social and friendly character of their meetings. With pleasure he saw so many of his medical colleagues present, anxious to do honour to the British Association.

Dr. NEIL ARNOTT, F.R.S., referred to the unanimity of feeling amongst the members of the medical profession generally; a feature not so universally seen in any other profession in the country. A French medical man who had lately visited him (Dr. Arnott), seemed surprised at the attractive character of the meetings of medical men in London; such meetings in France being the reverse.

The President proposed "The British Association".

Dr. R. G. LATHAM, F.R.S., spoke of the high character and position which the medical men held in the British Association, owing, in a great measure, to the *bona fide* character of their education. The peripatetic habits of the association encouraged a social feeling amongst the members of the profession.

Dr. SANDWITH proposed, "The Medical Visitors", and remarked that the local papers read before the British Association, he had no doubt, would be found peculiarly interesting to strangers. He was pleased to notice the active part which the medical men of Hull had taken in the proceedings of the association. The British Association was the means of bringing into existence the many creditable local papers read; and it was particularly adapted, by its intelligence and its genius, to evoke a spirit of emulation in science and philosophy, as well as that of commerce. He spoke as to the great edification received by the members of the profession here, from the elaborate scientific papers read at the meeting.

Dr. LANKESTER, F.R.S., had been a constant attendant of the British Association meetings for sixteen years, and therefore had some claim for his services. Although no purely medical section existed, the sections of natural history, physiology, and ethnology, were those in which medical men could take interest. Dr. L. spoke in favour of the objects of the association, and more particularly adverted to the friendly manner in which the members had been received in Hull.

Dr. WALKER ARNOTT, F.R.S., spoke in eulogistic terms of the reception of the members of the British Association, and proposed "The Resident Medical Men".

H. MUNROE, Esq., in reply, spoke of the great pleasure and unanimous feeling the profession had in inviting the members of the association to breakfast.

SECTIONAL MEETINGS.

Many of the Sections closed their business on this day.

A SOIRÉE

was held in the evening in the Music Hall.

WEDNESDAY, SEPTEMBER 14.

REPORT OF COMMITTEE OF RECOMMENDATIONS.

Several recommendations made by the Committee, involving grants of money, were adopted. The sum of £200 was granted to the Council for the maintenance of the Observatory at Kew; £20 to Mr. Rankine, Dr. Robinson, Professor Hodgkinson, and Mr. Ward, to prepare a report on the Cooling of Air in Hot Climates; and other sums, varying from £50 to £5, for reports on various scientific subjects.

The preparation of various other reports, not involving grants of money, was also resolved on.

The following resolutions were also passed:—

That the following papers, with the consent of the authors, be printed in full in the *Transactions* of the British Association for the year 1853:—James Oldham, Esq., On some of the Physical Features of the Humber; and On the Rise, Progress, and

Present Position of Steam Navigation in Hull. J. P. Bell, M.D., Observations on the Character and Measurements of Degradation of the Yorkshire Coast.

That the thanks of the British Association be given to the Parliamentary Committee for the unceasing attention they have paid to the interests of science, both in communications to Government, and in proceedings in the Houses of Parliament.

That the members of the British Association have learned with satisfaction that it is the intention of Government to direct, that in future, daily Meteorological Observations shall be made at sea, in correspondence with the plan adopted by the Government of the United States.

CONCLUDING GENERAL MEETING.

The concluding General Meeting was held in the Saloon of the Mechanics' Institute.

PRESIDENT'S ADDRESS.

The President spoke in high terms of approbation of the labours of the Local Committee, and of the whole of the arrangements. The rooms for the Sections had been more than usually convenient. He spoke also very highly of the local papers contributed, and of the public hospitality of the Local Committee and of the Mayor. Intellectually, as in every other respect, this meeting had been eminently successful.

Mr. W. SMITH, of Jordan Hill, moved, and the MAYOR seconded, a vote of thanks to the President.

MEMBERS PRESENT.

Professor PHILLIPS was happy to be able to announce that this had been a most successful visit. The returns made up to three o'clock that day, showed that there had been present 141 old life members, 13 new life members, old annual members 50, new 58, of associates 308, of ladies 230 [cheers], and of foreigners 6; making a total of 881. The amount paid by these was £904; and there had also been £22 received for books.

The meeting then adjourned.

[To be continued.]

CREWKERNE AND YEOVIL DISTRICT MEDICAL SOCIETY.

The sixth general meeting was held at Crewkerne on the 18th instant.

PROPOSED UNION WITH THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

After the ordinary business had been transacted, a deputation from the West Somerset Branch of the Provincial Medical and Surgical Association held a conference with the members. The present unrepresented and unorganised condition of the medical profession was fully discussed.

Mr. GILLET (the President of the Branch) showed how important it was that they should be united on certain points before they asked Parliament to legislate. He advocated the Provincial Association because it was the only society sufficiently large to have an influence with Government; and he believed that if it were as widely and as warmly supported by medical practitioners as it deserved to be, and as he hoped it would be, no ministry could refuse to listen deferentially to its opinion. It was only by sinking minor differences, and by uniting together in the support of the great principles upon which the profession is agreed, that real and permanent benefit would arise. By strengthening the power and augmenting the numbers of this Association, those reforms for which we are so anxious, can be best accomplished. By parliamentary representation, which also was most likely to be obtained by organising the ranks of the profession, we should have our interests (hitherto he was sorry to say treated without respect, as witness the new Vaccination Act) protected, and our station in society acknowledged by those who already knowing our usefulness nevertheless greatly undervalue it.

Dr. WOODFORD, the honorary secretary to the Taunton Branch also expatiated on the good effects already produced by the Association, and upon the still higher sphere of utility which he believed was now opening before it. He said that as the gentlemen present had borne witness to the excellence of the ASSOCIATION MEDICAL JOURNAL, the organ of the Association, he need not speak in its praise: but he would simply ask the members if they had not, in the weekly receipt of it, more than a "quid pro quo" for their guinea. But it was on far higher grounds that he advocated the cause of the Association. The Journal was only a means towards the accomplishment of great

ends. It was only by joining hand in hand in the support of one great influential national institution, such as the Association ought to be, and is now becoming, that the profession could make its advice or its remonstrance be heard in quarters where at times the welfare of the community demanded that they should be listened to with respect and deference.

Dr. Woodforde then entered into several details connected with the constitution and working of the Association. At the conclusion of his address, it was determined that the formal decision of the Yeovil and Crewkerne Medical Society should be made known to the West Somerset Branch of the Association as soon as the Honorary Secretary had communicated with the other members.

Dr. Tomkins, of Yeovil, and Dr. Cowdell, of Dorchester, were prevented from attending the meeting. Mr. Arden, the Honorary Secretary of the Dorset Branch, and Mr. Cory, of Bridport, the President, were invited to attend. The deputation consisted of Mr. Gillett, Dr. Woodforde, Dr. Kelly, Mr. Alford, Mr. Marchant, and Mr. Burt.

During the conference, it was suggested that if there were a sufficient number of members resident in the Crewkerne and Yeovil district, a meeting of the Branch might after the union be held once a year in the immediate neighbourhood, alternately with one in the Taunton and Wellington locality.

Since the meeting took place, of the proceedings of which the above is a condensed account, several of the members of the Society have signified their desire to join the Provincial Medical and Surgical Association.

ASSOCIATION INTELLIGENCE.

MEDICAL BENEVOLENT FUND.

At the Annual Meeting held in July, the Report for the past year was read and adopted. The following officers and Committee for the year were appointed:—

PRESIDENT:

Sir James Clark, Bart., F.R.S.

TRUSTEES:

Sir C. Hastings, M.D., D.C.L.	William Newnham, Esq.
Dr. George Burrows, F.R.S.	Joseph Toynbee, Esq., F.R.S.

OTHER MEMBERS OF THE COMMITTEE:

Edward Ambler, Esq.	Joha Ince, Esq.
John Bacot, Esq.	Dr. Bence Jones, F.R.S.
Wm. Bowman, Esq., F.R.S.	J. R. Martin, Esq., F.R.S.
John Churchill, Esq.	G. Pilcher, Esq.
Dr. John Conolly, D.C.L.	E. Saunders, Esq.
G. F. Dale, Esq.	William Self, Esq.
George Fincham, Esq.	Dr. Sibson, F.R.S.
Sir John Forbes, M.D., D.C.L.	Henry Sterry, Esq.
Joseph Hodgson, Esq., F.R.S.	Dr. West.
Thomas Hunt, Esq.	Erasmus Wilson, Esq., F.R.S.

TREASURER AND HONORARY SECRETARY:

William Newnham, Esq.

HONORARY SECRETARY TO THE COMMITTEE:

Joseph Toynbee, Esq., F.R.S.

[The Report will be found at page 734 of our account of the Swansea meeting.]

EDITOR'S LETTER BOX.

MEDICAL METEOROLOGY.

LETTER FROM J. C. BLOXAM, Esq., TO THE EDITOR.

SIR,—Some days ago, I wrote a few lines to you respecting the nature of the medical statistics that should be combined with meteorology. I have at present some cases under my observation which would serve to illustrate my meaning.

A lady, who is an habitual sufferer from indigestion, and has constantly a cutaneous eruption, has pain low in the left side, which is much aggravated by movement, and by any respiratory effort. The pain might be supposed to depend upon a rheumatic affection of the muscles, or on some irritation of the bowels or the kidney, or on the state of the spinal cord. A

lady, who is very subject to nervous affections connected with an asthenic state of the system as regards health and strength, has a severe stiff neck, the pain extending to the spine, down the arm, and down the side. Two children are suffering from sickness, anorexia, and severe pain in the stomach and bowels, attended in one with tendency to syncope, or pain in the loins. An elderly lady is attacked occasionally and temporarily with a paralytic condition of the arm and leg, with nervous shooting pains in the same limbs; she falls into a state which is described as being "like fainting"; she passes occasionally large quantities of pale coloured urine, some of which, that was passed whilst the quantity was not excessive, and the colour was not deficient, had the normal specific gravity and the normal acidity. An old man, with stethoscopic signs of dilatation of the ventricles of the heart, complains of severe palpitation of the heart, and such frequent and severe "faintings", that "they will be the death of him". He also complains of loss of appetite and distressing flatulence. A young woman, who has stethoscopic signs of impaired action of the heart, and I should say, contracted cavities, without either hypertrophy or dilatation, and who suffers habitually from palpitation and nervous pains in the cardiac and adjoining regions, is complaining at present of distressing palpitation, which is rather relieved than otherwise by exercise.

These cases, if classed as separate diseases, would appear to have very little connexion with one another; but, looking to the symptoms, I think they may all be considered to be connected with an impaired state of innervation; and this state, I have no doubt in my own mind, depends upon some meteorological phenomenon. I have not attempted to discover what the meteorological peculiarity is; and if I were to attempt it, I should probably fail. The barometer has been for several days above its average height, and there has been occasional fine and pleasant weather; but there is also frequent rain; there is fog in the valleys at night, and fog on the hill tops in the day. I think the peculiarity should be sought for in the electric state of the elements; not, however, in the absolute electric state of the atmosphere or the earth, but perhaps in the relative electric state of the upper regions of air, and the lower, or the earth's surface—a state that is probably *belonging* to the period of the year. I commonly observe that females affected with dilatation of the heart, or with nervous affections of the heart, or with chlorotic or anemic affections, complain of this period of the year; whilst those affected with hypertrophy of the heart complain in the spring.

I have not met with any cases of diarrhoea; but I think the present meteorological condition only requires some slight modification to determine the existence of such cases. I have observed diarrhoea and English cholera to occur when the temperature at night is very low compared with that of the preceding day; and, during a cholera epidemic, a cold clear night, following a hot day with constant sunshine, will often turn the scale against individuals, and determine an attack of cholera.

Much depends upon the mode in which meteorological changes are stated; and perhaps the least useful for the present purpose is that of stating mean values in the way that is usually done in forming meteorological tables. I think you have said, in your editorial capacity, that extreme values are more important; and no doubt they are so; but I am inclined to believe that well arranged mean values would be more useful still. Meteorological mean values for comparatively long periods, such as seasons or months, will serve to explain many phenomena of disease; but changes that occur in shorter periods of time than these would probably explain many more; and it would be a different order of phenomena that would be explained by mean values for each of these periods, as well as by extreme values. The great defect, I think, in the ordinary meteorological tables, for our purposes, is, that successive periods are observed which have no connexion either with meteorology or with pathology, but only with the calendar; one period beginning where the former ended. Now, there may be some very peculiar character belonging to the latter half of September and the first half of October; and yet this peculiarity may be entirely lost in the mean value of either September or October. Then we want mean values for shorter periods than months. I should say that ten days would be the most useful period; and it appears to me that these should not be arranged so that, the 1st—10th constituting the first period, the 11th—20th would constitute the second period; but the 2nd—11th would form the second period; the 3rd—12th the third, and so on.

I take much interest in the present meteorologico-pathological move; and I have no doubt that great results will be obtained

sooner or later from such an undertaking as you are entering upon; but I think we have as yet great difficulties to encounter.

I am, etc.,

JOHN C. BLOXAM.

Newport, Isle of Wight, Sept. 15th, 1853.

FINANCE AND MEDICAL REFORM.

LETTER FROM JOHN GRABHAM, M.D., TO THE EDITOR.

SIR,—Permit me to express a feeling of regret excited by that part of the financial statement which shews an *expenditure of £200 for Medical Reform!* I assure you, I belong to a not inconsiderable section of the Association, which would not willingly contribute sixpence towards *officious interference*; but holds the belief that it has defeated useful legislation; and that if Sir James Graham's first bill had not been opposed, our position would be far better than it is. Certainly, we should be correctly registered; and empiricism must have received a heavy blow by the penal clause against unauthorised assumption of titles. I hope our funds will be no more squandered on "presumptuous sins".

If our reformers had begun at the beginning, and considered the evils usually attendant on medical pupillage at hospital schools—so painfully described by Mr. Collins, of Harlow, in your last number—they might, indeed, have found legitimate occupation, and earned our gratitude by efforts to correct the chief source of our social degradation.

I am, etc.,

JOHN GRABHAM.

Lonsdale Square, Islington, September 19th, 1853.

[The vote of £200 to the Medical Reform Committee was carried at Oxford; but at the Swansea meeting no additional grant was passed, nor indeed was there any proposed. We are glad to learn, however, that a liberal fund is now being raised by voluntary contributions.

The subject referred to in the concluding paragraph of Dr. Grabham's letter at present engages our attention. The evil is painfully notorious; but we are anxious to have a somewhat matured plan for its remedy, before we make it a prominent topic of discussion.—EDITOR.]

FALSE AND GENUINE BASHFULNESS IN WOMAN.

LETTER FROM WILLIAM BAYES, M.D., TO THE EDITOR.

SIR,—I fully coincide with the remarks which you appended to my paper on Sterility.

In my desire to avoid too great prolixity, I fear I have fallen into the other extreme; and that, in my last paragraph, I have allowed my meaning to remain obscure.

Perhaps the word "timidity" would have conveyed a clearer impression than "bashfulness". Daily experience will convince any inquirer that immodesty is opposed to fertility.

"Genuine bashfulness" is, as you say, one of the "most charming attributes of woman", and is both health-bearing and health-born. It is not this to which I alluded in terms of repression; but a hyperæsthesia, a painfully nervous excitability, a diseased, atonic, unhealthy sensation, which no more bears comparison with its natural type, than does some sickly exotic of a greenhouse to its prototype growing luxuriantly in the tropics.

Genuine bashfulness is a thing of the heart—a glowing, impulsive feeling: the thing I spoke of is a parasite, planted in the brain, that chills and freezes, never warms.

I should not thus have troubled you, were it not that I fear that my silence might lead others to misconstrue the paragraph, which, I now perceive, said either too much or not enough.

Thanking you for pointing out what I otherwise might not have seen,

I am, etc.,

WILLIAM BAYES.

Marine Square, Brighton, Sept. 23, 1853.

MEDICAL EDUCATION.

HOSPITALS AND MEDICAL SCHOOLS IN ENGLAND.

(Continued from last Number.)

GUY'S HOSPITAL (SOUTHWARK).

CONSULTING PHYSICIAN: Dr. Bright. PHYSICIANS: Dr. Addison, Dr. Babington, and Dr. Barlow. ASSISTANT-PHYSICIANS: Dr. Hughes, Dr. G. Owen Rees, and Dr. Gull. SURGEONS: Mr.

Cock, Mr. Hilton, and Mr. Birkett. ASSISTANT-SURGEONS: Mr. Alfred Poland and Mr. T. Callaway. OBSTETRIC PHYSICIANS: Dr. Lever and Dr. Oldham. SURGEON-DENTIST: Mr. T. Bell. SURGEON OF THE EYE INFIRMARY: Mr. France. APOTHECARY: Mr. Stocker.

This hospital contains 549 beds.

Students must give satisfactory testimony as to their education and conduct; they will be required to pay £40 for the first year; £40 for the second; and £10 for every succeeding year of attendance. The sum of £100 in a single payment entitles the student to a perpetual ticket.

Dressers, clinical clerks, assistants, resident obstetric clerks, and dressers in the eye ward, are selected from those students who have attended a second year.

MEDICAL SCHOOL. WINTER SESSION. Medicine. Dr. Addison; M., W., and F.

Surgery. Not announced; Tu., Th., and Sat.

Anatomy, Descriptive, Surgical, and Pathological. Mr. Hilton and Mr. Birkett; daily.

Physiology. Dr. Gull; M., W., Th., and Sat.

Demonstrations on Anatomy, in the dissecting room. Mr. Callaway and Dr. Habershon; daily.

Demonstrations in Morbid Anatomy. Daily.

Chemistry. Dr. Alfred S. Taylor; Tu., Th., and Sat.

Natural Philosophy. Tuesday, at seven.

Moral Philosophy. Rev. T. H. Bullock, Chaplain to the Hospital.

Clinical Medicine. Dr. Addison, Dr. Babington, and Dr. Barlow.

Clinical Surgery. Mr. Cock, Mr. Hilton, and Mr. Birkett.

Clinical Lectures on Midwifery and Diseases of Women. Dr. Lever and Dr. Oldham.

SUMMER SESSION. Materia Medica. Dr. Owen Rees; Tu., Th., and Sat.

Botany. Mr. Johnson; Tu., Th., and Sat.

Medical Jurisprudence. Dr. Alfred Taylor; Tu., Th., and Sat.

Midwifery. Dr. Lever and Dr. Oldham; daily.

Practical Chemistry. Dr. Odling; M., W., and F.

Demonstrations on Cutaneous Diseases. Dr. Addison and Hughes; M., at one.

Clinical Lectures. Dr. Hughes, Dr. Owen Rees, and Dr. Gull.

Regional Anatomy. Mr. Hilton or Mr. Birkett.

Dental Surgery. Mr. Bell and Mr. Salter.

Pathological Anatomy. Dr. Lloyd.

SCHOOL OF ANATOMY AND MEDICINE (1 GROSVENOR PLACE).

WINTER SESSION. Medicine. Dr. Daniell and Dr. Sibson; W. and F. Fees, £5:5, and £6:6.

Surgery. Mr. Pilcher and Mr. Smith; Tu., Th., and Sat. Fees, £3:3, and £5:5.

Descriptive and Surgical Anatomy. Mr. G. E. Blenkins and Mr. J. R. Lane; daily. Fees, £6:6, and £8:8.

Anatomy and Physiology. Mr. Lane, Mr. G. E. Blenkins, and Mr. J. R. Lane; daily. Fees, £6:6, and £8:8.

Chemistry. Mr. Rodgers; M., W., and F. Fees, £5:5, and £6:6.

SUMMER SESSION. Materia Medica and Therapeutics. Dr. Lankester; daily, except Sat. Fees, £5:5, and £6:6.

Botany. Dr. Lankester; M., W., and F. Fees, £3:3, and £4:4.

Medical Jurisprudence. Mr. Warder; M., W., and F. Fees, £3:3, and £4:4.

Midwifery. Mr. Bloxam; daily, except Sat. Fees, £3:3, and £5:5.

Practical Chemistry. Mr. Rodgers; Tu., Th., and Sat. Fee for course, £3:3.

Microscopical Anatomy. Mr. G. E. Blenkins.

General fee to the whole of the courses required by the College of Surgeons and the Apothecaries' Company, including one course of Practical Chemistry, forty-two guineas, half of which may be paid on the entrance of pupils, and the remaining half in January.

Clinical prizes will be awarded for the best reports of medical and surgical cases occurring in the wards of the hospital at which the student attends.

NEWS AND TOPICS OF THE DAY.

[Continued from page 852.]

COLLEGE OF PHYSICIANS AND SURGEONS OF LOWER CANADA. The triennial meeting was held at the Court House of Three Rivers on Wednesday, 13th ultimo. Dr. Morin in the chair.

The secretary read a report, from which it appeared that during that period seventy-five students presented themselves before the governors for license, and that of this number sixty-one were admitted to practise as physicians, surgeons, and accoucheurs; two as chemists and druggists; and twelve were rejected. Seventy gentlemen came up for preliminary examination, of whom sixty passed, and ten were remanded.

The treasurer submitted his statement, showing a balance of £127:16:9 to the credit of the College.

On motion by Dr. David, seconded by Dr. Russell, it was unanimously resolved that a delegate be named to attend the American Medical Convention, and that the secretary be instructed to ascertain whether the person so attending can take his seat as a representative. And it was further resolved, that the President-elect be the first delegate, and afterwards the delegate chosen by the Board of Governors.

The ballot for the election of governors resulted in favour of the following gentlemen:—

QUEBEC. City: Drs. Morin, Fremont, Marsden, Sewell, and Landry. District: Drs. Michaud, Marmette, De Salles, La-terriere, De Chene, Von Iffland, Dubois, and Boudreau.

MONTREAL. City: Drs. Holmes, Munro, Campbell, Jones, Sutherland, Peltier, Bibaud, and Tavernier. District: Drs. Weillbrenner, Sabourin, Chamberlin, Brigham, Boutillier, Valois, and Foster.

DISTRICT OF THREE RIVERS: Drs. Badeau, Gilmour, and Dubord.

DISTRICT OF ST. FRANCIS: Drs. Glines, Fowler, and Johnson. The newly appointed governors having met together, elected the following office-bearers (the two first and the fifth unanimously):—

President	Dr. Holmes.
Vice-President for Montreal	Dr. Boutillier.
Vice-President for Quebec	Dr. Fremont.
Registrar and Treasurer	Dr. Jones.
Secretary for Montreal	Dr. Peltier.
Secretary for Quebec	Dr. Landry.
H. PELTIER, M.D.	} Secretaries.
J. E. LANDRY, M.D.	

There are now seventy-five registered members enrolled on the books of the College:—forty-three to Montreal, thirty-one to the city, and twelve to the district; twenty-five to Quebec, nineteen to the city, and six to the district; five to the district of St. Francis and Three Rivers; and two to Three Rivers. Of these, but thirty-eight were present, one of whom was entrusted with sixteen proxies.

IMPUDENCE OF A FILTHY QUACK. A case was last week brought before Sheriff Henderson of a somewhat novel nature. The pursuer was Mr. Patrick O'Neill, designating himself "surgeon, Dundee", and the defender Mr. William Norrie, clerk in the Dundee and Arbroath Railway Company's office. The account charged on was "To damage and loss sustained by me on account of your having destroyed, dilapidated, and defaced my bills, on the 9th day of August, 1853, which were posted on Broughty Castle and otherwise on several other occasions, and also for attempting to destroy my reputation as a medical adviser; moderately estimated at £5." Copies of the "bills defaced" were produced in Court, the nature and contents of which may well be guessed. Mr. William Kerr, writer, who appeared for Mr. Norrie, submitted to his Lordship if the productions exhibited were of a nature to be put on the walls of such a public place as Broughty Castle, the constant resort of respectable people at this season. In addition, Mr. Kerr produced a mandate from the manager of the railway, to whom the castle belongs in property, authorising Mr. Norrie to prevent any person putting up bills on the walls: and he said that he was prepared to adduce evidence that the bills were not taken down by Mr. Norrie, but by the regular servants of the company. Mr. Kerr also proceeded to put some questions to the pursuer, with the view of establishing that he had no claim to the title he assumed. In answer to these questions, the pursuer admitted that a few years back he earned his living by manufacturing shoe blacking, which he vended through the country along with lucifer matches, and that in the course of his peregrinations he on one occasion en-

countered a strange adventure at the Castle of the Laws with a coloured servant of the then proprietor, and which afterwards formed the subject of judicial proceedings. The charge against Mr. Norrie was dismissed. (*Dundee Warder.*)

APOTHECARIES' HALL:—PASS LIST. Thursday, August 18th, 1853:—William Altham, Bentham, Yorkshire; William Roger Banks, Birmingham; Edward John Longton, Southport, Lancashire; William John Newman, Sydney; George Mayris Pittcock, Deal, Kent; Peter Williams Rolston, Devonport; George Stopford Taylor, Sheffield; Thomas M. Williams, Wellow, near Oberton, Notts.

Thursday, August 25th:—Thomas Creed, Ballinstona; Benjamin Davies, Froodvale, Carmarthen; Frederick Abell Humphry.

Thursday, September 1st:—John William Farley Dadley, Patrington, Yorkshire; Fergus Ferguson, Bolton; William Johnson Dawson Hutchinson, Yorkshire; William Younge Jeeves, Sharrow Grange, Yorkshire; George Kirk, Middlesborough-on-Tees; Charles West Roberts, Bristol; Samuel Thorpe, Manchester.

Thursday, September 8th:—John Holmes Jephson, Birkenhead; Sydney Jones; James Douglas Kelly, Liverpool; George Mundie, Dalston.

APPOINTMENTS.

*[*An asterisk is prefixed to the names of Members of the Association.]*

*BIRKETT, John, Esq., elected Surgeon to Guy's Hospital, in the room of the late Bransby Cooper, Esq.

CALLAGHAN, Charles, Esq., appointed House-Surgeon to the Kent County Ophthalmic Hospital.

CALLAWAY, Thomas, Esq., elected Assistant-Surgeon to Guy's Hospital.

FIFE, George, M.D., of Newcastle-on-Tyne, appointed Physician to the Queen's Hospital, Birmingham, in the room of the late Dr. Samuel Wright.

JORDAN, R. C. A., M.B., re-appointed Medical Tutor in Queen's College, Birmingham.

NEVINS, J. Birkbeck, M.D., elected Assistant-Surgeon to the Eye and Ear Infirmary, Liverpool.

*SYMSON, T., Esq., elected Surgeon to the Lincoln General Dispensary.

TAYLOR, R. Hibbert, Esq., elected Surgeon to the Eye and Ear Infirmary, Liverpool.

OBITUARY.

*[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]*

CROOM, George, Esq., Surgeon, at 3, Argyle Square, Edinburgh, aged 43, on September 14.

DAVIS, Richard, Esq., of Ramsbury, Wilts, at St. Aubin's, Jersey, aged 42, on September 5.

EDWARDS, John, Esq., Surgeon, at Dorchester, aged 54, on September 15.

HARRIS, Walter William, Esq., Assistant Surgeon 1st West India Regiment, at Kingston, Jamaica, lately.

KENNY, M. W., Esq., Staff Surgeon in the Indian army, lately.

LINTON, Charles, Esq., Surgeon, one of the medical officers at the battle of Trafalgar, aged 70, on September 3.

NORTON, Matthew, Esq., Surgeon, of Gloucester Place, New Road, at Jersey, aged 75, on September 2.

POWELL, J. G., Esq., Surgeon, at Bristol, where he had practised nearly fifty years, aged 73, on Sept. 12.

PRICE, Charles, Esq., Surgeon, at Brighton, aged 77, lately.

STALLARD, John Pinfold, Esq., Surgeon, at Leicester, aged 61, on September 7.

*TOMS, William, Esq., Surgeon, at Barnfield House, Kingsbridge, Devon, aged 55, on September 18.

WALLACE, John Andrew, Esq., Surgeon, at Carlisle Terrace, Bow, Middlesex, by suicide with prussic acid while labouring under mental depression from pecuniary difficulties, aged 51, on September 2.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XL.

LONDON: FRIDAY EVENING, OCTOBER 7, 1853.

NEW SERIES.

THE MEDICAL METEOROLOGY OF THE ASSOCIATION JOURNAL.

Our arrangements for carrying into effect the plan of daily meteorological observation and record, already described, are now completed; and the first page of observation is given in this day's number. The delay which has taken place has been occasioned by circumstances which require a little explanation.

In consequence of numerous applications addressed to Dr. MOFFAT for information respecting ozone, that gentleman had consigned the preparation of the ozone test-paper to Mr. JOHN COX of Peckham, with full instructions as to the mode of testing, etc. To this we alluded in a foot-note of our introductory article on medical meteorology (p. 748). Just at the time of the appearance of that article, Dr. Drew of Southampton issued a circular among meteorological observers, stating that he had lately had an interview with Dr. Schönbein of Bâle, the discoverer of ozone, and inviting British observers to make records on Dr. Schönbein's plan of notation, and transmit quarterly their ozone-tables to Dr. Schönbein. The *modes of notation* respectively adopted by Drs. Schönbein and Moffat differ considerably from each other; and it is hardly necessary to say that a want of uniformity of modes would be a serious disadvantage. Argument with regard to the respective merits of the two plans would probably be inconclusive, and would consume valuable time. The shortest way to obtain uniformity was by concession. With a modesty characteristic of the true devotee of science, Dr. Moffat most readily conceded the point, and has consented, with the other observers, to adopt Dr. Schönbein's method of notation. Deference to the claims of the discoverer, and a wish to facilitate practical co-operation, are the motives by which Dr. Moffat has been guided.*

Any discussion of the respective merits of the two plans of notation would now be out of place, as the question is practically settled; but we may be allowed to remark, that the experience of Dr. Moffat in observations on ozone, with special relation to diseases, is probably greater than that of any other observer, not excepting the discoverer. For a period of nearly six years, Dr. Moffat has unremittingly pursued his quiet course of daily, almost hourly, observations; thus giving an example of that patient and steady attention to phenomena which must ultimately lead to sound inductions, and to a knowledge of general laws. This course of observation was commenced almost immediately after the announcement of the discovery of ozone, in April 1848. Various formulæ for the preparation of the test-paper were tried, and a table of notation was formed. As early as 1848, at the annual meeting of the British Association for the Advancement of Science, held at Swansea, Dr. Moffat's observations on ozone were noticed, and speci-

mens of his test-paper were exhibited. An abstract of these proceedings was given in the *Athenæum*. A paper on "Medical and Agricultural Meteorology and Atmospheric Ozone" was read at the British Meteorological Society, on March 23rd and April 27th, 1852. Another paper on the same topics, but particularly treating of the atmospheric causes of the potato disease, was read in May last; and abstracts of these papers were published in the *Athenæum*.

This short statement of Dr. Moffat's services to science with regard to ozone observations seems necessary to enable our readers to appreciate fully (as we do), that gentleman's modesty in relinquishing, for the sake of uniformity, and for the interests of science, his own plan of notation, sanctioned as it has been by long experience and a considerable degree of success. We will conclude by expressing a hope that, shortly, the results of Dr. Moffat's extensive course of observations may be given to the readers of this Journal.

Having thus explained the causes of some little delay, we may advert with pleasure to the fact that an increased attention to meteorology is already observable. Not fewer than *sixty gentlemen*, residing in various parts of the country, are about commencing observations on ozone, in concert with the discoverer, Dr. Schönbein. Judging from the communications which we have received from numerous influential members of our Association, and from others eminent in science, our own scheme of medico-meteorological records has excited very great interest both at home and abroad.

A good beginning has been made this day; and now we have only to proceed in the proposed course of persevering and faithful record of observations, in order to arrive at important inductions. When daily meteorological changes and daily accessions of diseases and deaths shall have been faithfully noted, side by side, and for a considerable length of time, we shall have tables of data from which we may soundly generalize and make inductions. As we have said in our article of August 26th, relations between health and atmospheric changes, now only suspected or supposed, may, by industrious and strict observations, be brought out from the wide domain of hypothesis, and become established among the truths of science. That important hygienic precepts and sanitary reforms must sooner or later follow the labours upon which we are now entering, is too evident to require argument.

PRIVATE PRACTITIONERS AND THE NEW VACCINATION ACT.

No words are sufficiently strong to represent the alarm and disgust which the New Vaccination Act is creating among *private practitioners* throughout the kingdom. During the last week, we have received no end of letters on the subject. The union medical officers, however, as a body, seem to be satisfied, or at least they are quiet; and at this there need be no surprise, because none of them are losers, and some are pecuniarily gainers, though their vaccination services are still, in our opinion, greatly undervalued. Sir John

* Mr. John Cox, of 3, Rye Lane, Peckham, has received the agency of Schönbein's test-paper and ozonometer.

Pakington committed a great blunder when, in spite of the combined resistance of the medical press, and of the profession, he recklessly carried the act through Parliament, after Lord Palmerston had reassured the profession by stating, on the 1st of August, to Dr. Cormack, Dr. Fraser, and Dr. Semple—a deputation from the Metropolitan Counties Branch of our Association—"that the request for delay seemed very reasonable; that he thought that Sir John Pakington would be satisfied this session with having had the bill amended in Committee, and that it would be submitted to their deliberate consideration. Lord Palmerston stated that he had little doubt that the bill would, under all the circumstances of the case, be postponed until next session." As a statesman, we say that Sir John Pakington committed a *blunder*, because we believe that it was from good motives that he resolved to carry his measure in defiance of the united demand for delay on the part of the profession. However that may be, we have to deal with the present, and not with the past. An act of Parliament has been passed, which most wantonly places private medical practitioners at the mercy of poor-law guardians, and which, if not altered immediately, is certain—we speak from letters before us—to excite innumerable heartburnings between private practitioners and union surgeons, and seriously to interfere with the former in their relation to their patients among the working classes and tradespeople.

While we speak thus strongly against the part which Sir John Pakington has acted in this business, and express our determination to agitate for justice and fair dealing till they be conceded, we ought not to refrain from stating that unlooked for elements of good may yet be extracted from the working of this act, especially from the registration of all legally qualified practitioners, which has, within the last month, been carried out all over the kingdom by the Registrar-General.

Private practitioners must arise in one united mass, and give government no rest till they are protected in the discharge of their professional duties from the interference of poor-law guardians, to which they are cruelly exposed by the looseness of the new act. Our readers will find this referred to by a correspondent in a subsequent page, and it is the burden of many letters now before us. It is not, however, by letters and leaders that all can be achieved: united action is required. If the act be amended, it may yet produce good effects: but, in its present state, it is unworkable and unjust.

THE EAST SURREY CHOLERA SOCIETY.

WE last week promised to "speak of the formation of local cholera committees by members of the Association, and other respectable practitioners willing to co-operate with them". We are glad to find that the duty of establishing such committees of public health is generally recognized by the profession, and that in various places the medical men are co-operating with the clergy, not only in preparing to meet the pestilence, but also to secure data, while it is present, for subsequently preparing an accurate history of its progress and character. Whilst we strongly advise our professional friends to co-operate with the other members of society in carrying out these laudable schemes, we would urgently request them to bear in mind that, unless they *take the lead and act in concord* in their respective neighbourhoods, local cholera committees cannot possibly be of

the slightest use. We had intended to offer a few suggestions upon the manner in which these committees ought to be constituted, and the plan of working which they ought to adopt; but, as we find that the medical men of East Surrey are already organising themselves as a "Cholera Society", we defer enlarging upon the subject till we can lay before our readers the prospectus of this new institution, which, we have no doubt, will be judiciously and energetically conducted.

The following advertisement appears in the newspapers of this day. We reprint it here, in the hope that, if any of the numerous members of the Association resident in East Surrey have not already responded to the call, they may do so with as little delay as possible.

"EAST SURREY CHOLERA SOCIETY. It is proposed to form a Society for the observation of Cholera in East Surrey. Qualified Practitioners of Medicine willing to co-operate for this purpose are requested to communicate immediately with the Provisional Committee.

"B. W. RICHARDSON,

"Hon. Sec. to the Prov. Committee.

"Mortlake, October 5th, 1853."

We understand that, during next week, a preliminary meeting will be held at Richmond, Mortlake, or Croydon; and that, subsequently, local sub-committees will be formed for the different towns.

THE MARCH OF CHOLERA.

HITHERTO, the progress of the pestilence in 1853 corresponds remarkably with its career in 1831-32, and in 1845-49. Both of these epidemics began at the end of harvest, and continued for about fifteen months. The following passage from the Cholera Report is correct as regards the former epidemics, and is also applicable to the present:—

"The cholera in England kept pace in its development with the wheat plant, which took root in October, germinated in the winter, flowered in June, filled in July and August, was cut down by the reaper before the first week in September, when cholera was most rife; and would have been dead ripe in October and in November, when cholera ceased."

We may, therefore, expect the outbreak to subside now, and to burst forth again in spring, reaching its climax next August.

Newcastle has been very much more severely visited this year than any other town in the kingdom: in fact, the cases which have occurred in other places have been few in number. On the 3rd of October, it was officially reported that "the total number of deaths in Newcastle during the present outbreak had been 1,413. In the same period (*viz.*, the first thirty-three days), during the prevalence of epidemic cholera in 1831-32, the number of deaths was only 229.

We shall in due time give as complete a history of the epidemic as can be obtained; but from week to week we shall call attention only to its more striking features.

MEDICAL EDUCATION IN SCOTLAND AND IRELAND in our next number.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London; or to the office of the Journal. Letters requiring immediate attention, and revised proofs ought invariably to be sent to Putney.

ORIGINAL COMMUNICATIONS.

CLINICAL ILLUSTRATIONS OF SOME DISEASES OF THE ŒSOPHAGUS.

By C. E. REEVES, B.A., M.D.

SIMPLE ULCERATION.

SIMPLE ulceration of the Œsophagus presents the same character as that of the stomach. It generally commences in the mucous membrane; but it may arise in the submucous cellular tissue from abscess, from tubercular deposits, or from thickening occurring either above or below the point where it exists, from pressure by an enlarged Œsophageal gland, by tumours pressing on the Œsophagus, by aneurism, or by ossification of the rings of the trachea; from abscess of the lungs, or of the cellular tissue external to the canal; or in consequence of caries of the vertebra.

It is extremely rare to meet with more than one ulcer, unless where abscesses are immediately in contact: except when it arises from follicular inflammation; then the ulcers will be numerous. This last form of ulceration is only met with in acute Œsophagitis.

Simple ulcers vary in size and shape. When small, they are generally oval or round; but when large, they are more or less irregular. Their depth and appearance will vary; the mucous membrane may be only destroyed, the submucous cellular membrane participating or not; the muscular substance being laid bare, or in part or wholly destroyed, leaving only the external membrane; or the walls of the trachea may be more or less destroyed. It rarely happens that the edges of the ulcer present indications of chronic thickening. A soft and spongy or somewhat infiltrated condition, with a state of vascular congestion of the surrounding parts, is the most frequent. When perforation into a cavity has taken place, they usually present all the characters of perforated ulcer of the stomach; namely, as if punched out.

The point of the canal opposite the bifurcation of the trachea is the most frequent position, and Albers (*Atlas der Pathologischen Anatomie*), has collected the following cases from various sources to prove this.

	Cases.	On the bifurcation.		Other situations.
		M.	F.	
Keppelhout - -	2	2		
Sandfort - - -	1		1	
Kunze - - - -	1	1		
Wade - - - -	1	1		
Hecking - - -	1	1		
Albers - - - -	4	4		1 external to the bifurcation.
Heister - - - -	1			Position not named.
Baillie - - - -	1			Position not named.

In eighteen deaths which he has also collected, the following were the ages of the patients:—

Ages.	Males.	Females.
From 1 to 10 years	1	0
" 10 to 20 years	1	1
" 20 to 30 years	1	0
" 30 to 40 years	1	1
" 40 to 50 years	2	0
" 50 to 60 years	4	2
" 60 to 70 years	1	0
" 70 to 80 years	1	0

In two cases the age is not mentioned.

He remarks, that in three deaths before 20 years, two occurred in scrofulous subjects, and one in a tuberculous person.

The following cases have been collected by myself, some of those cited by Albers being unavoidably included:—

Age.	Sex.	Position in canal.	Terminations.
53	F.	Upper part.	Bronchitis, not caused by disease.
67	M.	Where it passed under aorta.	Exhaustion.
Adult.	M.	Opposite the bifurcation of trachea.	"
7	F.	Just above diaphragm.	Perforation into pleura.
7	F.	"	"
Adult.	M.	Just before passing to the right.	"
—	M.	Above the cardia.	"
—	M.	"	"
17	M.	Not named.	"
46	M.	Near centre.	Perforation of aorta.
51	M.	3 in. above cardia.	"
Aged.	F.	Not named.	"
Aged.	F.	Upper third.	Erosion of small vessels.
25	F.	Lower third.	Perforation of pericardium.
12	M.	"	Abscess of right lung.
58	M.	"	Ditto.
Adult.	M.	Not named.	Ditto.
54	M.	"	Ditto, and perforation of trachea.
50	M.	Middle third.	Ditto, ditto.
34	M.	Opposite fourth dorsal vertebra.	Ditto, and from it into pleura.
51	M.	Upper part.	Perforation of trachea.
55	M.	Above bifurcation of trachea.	Ditto: gastritis, and colonitis.
60	M.	Below bifurcation of trachea.	Abscess in walls, and perforation of trachea.
3	M.	Half an inch below bifurcation.	Perforation of right bronchus.
63	M.	"	"
12	—	Middle third.	Abscess in walls.
Adult.	F.	Opposite fifth or sixth dorsal vertebra.	Abscess in posterior wall, caries of vertebra.
52	F.	Just below bifurcation of trachea.	Abscess in walls.
60	M.	Upper third.	Abscess in post. walls.
60	F.	"	Destruction of thyroid gland; perforation of larynx.
—	F.	"	Narrowing below ulcer.
42	M.	"	"
36	F.	Lower third.	Narrowing above ulcer.
59	F.	Near cardia.	Two sinuses entering lungs.
Adult.	F.	Lower third.	Abscess below trachea, commencing with Œsophagus and trachea.

In these cases, thirty-five in number, thirteen occurred in females, and twenty one in males: in one case the sex was not named.

CASE I. ULCERATION OF THE SUPERIOR PART OF THE ŒSOPHAGUS: DEATH FROM BRONCHITIS. F., aged 53, had good health until within the last eight months, when, after an attack of inflammatory affection of the throat, she began to experience a sensation as if a hair was arrested there. This produced constant hawking, nearly every minute, of clear mucus. The sensation increased in extent within the last four months; and she then observed that the mucus became streaked with yellow matter, and occasionally with blood. From the commencement, she had suffered from severe heat and dryness in the throat, and a constant desire for cold drinks. On the appearance of the blood, she began to experience difficulty in swallowing, particularly anything hard, or any stimulants or sour substances. Insensibly she got into the habit of taking none but the blandest kinds of food. During the last ten weeks, the quantity of fluid

hawked up had increased; and she found that, if she did not clear the throat well, the first mouthful of fluid was very apt to be rejected. For the last three weeks, cough had begun to trouble her, and her voice had become hoarse; and with the cough, for the last two months, there had been a rather copious expectoration. On examining the throat, it was pale, and covered with mucus; but, on her making an effort to swallow, it was seen to be red below. The right side of the œsophagus, below the thyroid cartilage, in the vicinity of the upper part of the trachea, on pressing with the finger, was painful, and hawking and retching were produced, followed by the ejection of about a teaspoonful of muco-purulent matter and mucus. The thyroid on this side seemed enlarged. The use of a strong solution of nitrate of silver, applied by means of a piece of sponge attached to a wire, was had recourse to: this seemed of considerable benefit, with milk diet. But she was seized with bronchitis, then very fatal; and she sank in four or five days.

A small ulcer existed in the œsophagus, of the size of a sixpence: the parts around it were vascular, and slightly thickened; the mucous and submucous membranes were destroyed, and some of the muscular fibres exposed. The trachea was, opposite the ulcer, red and vascular to the extent of a half-crown, and covered with muco-purulent matter; the chordæ vocales were thickened; and the thyroid was enlarged.

CASE II. ULCERATION OF THE ŒSOPHAGUS OPPOSITE THE BIFURCATION OF THE TRACHEA.* A gentleman had suffered for some weeks from gradually increasing difficulty in swallowing. Fluids met with an obstruction about the middle of the œsophagus, which retained them about a minute, and then rejected them, mixed with viscid purulent matter. After this had occurred twice or three times, the passage became clear, and they then descended in small quantities into the stomach. He sank soon after.

An ulcer of a spongy character existed in the canal, opposite the bifurcation of the trachea. The canal was so narrowed by it, that, although it was contained in a kind of pouch, the anterior wall of which was formed by the mucous membrane of the trachea, fluids could scarcely pass.

CASE III. ULCERATION, WITH OSSIFICATION OF THE HEART. M., aged 67,† until four months ago, had good health; he then began to suffer pain in swallowing, just as the food was entering the stomach; and, before it had been there long, to vomit it up. He was now much worse; food did not remain down more than two minutes. The pain was constant, extending outwards under the left false ribs; the pulse 100, feeble, and intermittent. Broth clysters were thrown up. He gradually sank, and died seven months from the commencement of the illness.

A large ulcer, two inches long and one inch broad, existed in the œsophagus, at the point where it passed under the aorta. Fluid existed in both sides of the chest, and the stomach was slightly inflamed. The substance of the heart was ossified; the ossification followed the course of the septum, from the base to apex; in some places it was two inches broad, and of unequal thickness. The pericardium was thickened, and adhered to the heart.

Baillie, in page 51 of his *Morbid Anatomy*, illustrated with plates, gives a drawing of a simple ulcer of the œsophagus, but no history of the case.

Billard (*Maladies des Enfants*) mentions the case of a female infant, seven days old, which was brought to the infirmary on the 2nd of May, with the members hard and cedematous. It had green diarrhoea, and nearly constant vomiting of glairy matters, with frequent regurgitation after drinking. The heart's action was weak, and the skin cold. On the second day, it vomited green liquid, and died the same evening. An ulcer existed at the lower extremity of the œsophagus, six lines long and four broad. The mucous membrane was destroyed, and the base of the ulcer was formed of cellular tissue alone.

ULCERATION, WITH PERFORATION OF THE WALLS OF THE ŒSOPHAGUS INTO THE PLEURAL CAVITIES.

CASE I. A female, aged 7,* had been brought up almost entirely on bread since she was weaned. She had been suffering for the last day or two from constant retching, pain in the epigastric region, and thirst. The abdomen was hard; the tongue clean and red. Demulcents, with mint tea and liquor opii sedativus, were ordered; and by the next day the retching was less severe. By the advice of a medical man, who considered her to be labouring under disorder of the stomach, an emetic mixture was given, and I ceased to see her. She sank thirteen days afterwards.

One inch above the cardia, an ulcerated opening, with smooth edges, existed, communicating with the left pleural cavity. The mesenteric glands were enlarged, but all the other viscera were healthy.

CASE II. F., aged 7,‡ of good general health, was seized with diarrhoea, which lasted several days. After dinner one day, she was seized with vomiting. During the night, fever set in, with severe thirst and faintness; next day, nausea and convulsions were joined, followed by extreme feebleness, violet hue of face, dilated pupil, burning skin, with very difficult and painful deglutition. She died thirty-six hours from the commencement of the vomiting.

In the œsophagus, from an inch and a half to two inches above the diaphragm, was an oval aperture, four-fifths of an inch long, and two-fifths of an inch broad. The right side of the pleura was filled with a brown fluid, in which floated dark green flocculent shreds.

CASE III. A man§ much addicted to drink had a relapse from delirium tremens, and died suddenly in a convulsive fit. For a year before his death, he had suffered from dyspeptic symptoms, for which many remedies had been taken in vain. During the last two days, he had had several loose motions. On the morning of the day of his death, he awoke, after a good night, quite free from dyspepsia; at two P.M. he fell into a convulsive fit, and died three hours afterwards.

In the œsophagus, immediately before its transition to the right, an opening, about the size of a crown-piece, existed, with smooth edges, communicating with the pleural cavity, which contained from twelve to sixteen ounces of brown fluid. The pericardium adhered to the heart. The liver was large, grey, and soft. The arachnoid was thickened: both it and the ventricles contained some fluid.

Mr. T. W. King, under the head of Digestive Solution of the Œsophagus (*Guy's Hospital Reports*), has published the case of a man suffering from diabetes, who died in a convulsive fit. At the *post mortem* examination, one side of the œsophagus, just above the cardia, was found eroded. He does not state the aspect of the perforation, whether it presented the characters of an ulcerative one, or of one arising from digestive solution.

Dr. Copland has recorded a case of a young man of drunken habits, who died after suffering a few days from symptoms of affection of the œsophagus. A perforated opening was found near the cardia. I quote the case from memory. In his remarks on the subject, he considers the case of Mr. King to have been analogous.

CASE IV. A student, aged 17,§ of weak constitution and contracted chest, was seized with severe discharge of blood from the mouth, which, after placing his life in great danger, declined. Pus mixed with blood was then excreted. This again was followed by spitting of blood, which lasted two months. After this, copious and frequent discharges of blood from the nose came on. He had also a burning pain above the left orifice of the stomach, which resisted every remedy that was employed. Respiration was always difficult, and he could lie only on the right side. He sank gradually.

In the œsophagus, two inches above the diaphragm, an

§ Heister, in Acta Natur. Cur. Obs., clxxxiii.

aperture existed, an inch in diameter; and through this the fluid found in the chest must have made its way, as it smelt strongly of cordial water.

ULCERATION WITH PERFORATION OF THE AORTA, SMALL VESSELS, AND PERICARDIUM.

CASE I. PERFORATION OF THE AORTA. M., aged 46,* on the 30th of April, 1837, after indulging freely in beer, drank a considerable quantity of ardent spirits. The next morning, he felt generally indisposed, with pain in the breast and stomach. An emetic gave him considerable relief. On the 2nd of May, he complained of loss of appetite, severe thirst, and severe pain under the sternum, accompanied with slight cough. On the 6th, difficulty was experienced in swallowing; and, at a spot in the upper third of the canal, fluids seemed to regurgitate before descending into the stomach. Leeches and demulcents were ordered. The symptoms continued up to the 19th with little alteration, except an evening exacerbation, when a small quantity of blood was brought up. On the 20th, it amounted to four pounds. Blood was also passed by stool. He sank the same day.

In the œsophagus, near its centre, a small ulcer existed, surrounded by traces of inflammation. The ulcer was half a line long and three lines broad: it had penetrated the aorta at the point where the left carotid was given off.

CASE II. M., aged 51,† a week previously first complained of deep seated pain at the top of the sternum, shooting to the spine. One hour before being seen, he had had profuse hæmorrhage, of a bright frothy character, from the mouth. Acetate of lead was given internally, and ice was applied to the chest. The next morning, his pulse was 100, small; the respiratory murmur was deficient, with dulness on percussion in the upper part of the left lung. Half an hour after this, he had a return of the hæmorrhage, which proved fatal.

In the œsophagus, three inches above the cardia, a circular opening existed, three and a half inches in diameter, with smooth edges. Below it, an irregular erosion existed, involving partly the œsophagus, and partly the stomach. In the aorta, at the point where the descending part of the arch terminated, and corresponding with the first named ulcer, but somewhat higher, an irregular opening, with jagged edges, was found. The walls of the artery were much thinner at this point than at any other; and, half an inch lower down, an atheromatous patch existed, the centre of which was in a state of ossification. A free communication existed between the aorta and the œsophagus. The stomach was distended with a large coagulum of blood. The duodenum contained loose coagula, and the rest of the intestinal canal contained blood in a fluid state. In the upper part of the left lung, some crude tubercles existed.

Van Doveren mentions the case of an old woman, who died from discharge of arterial blood from the mouth. An ulcer was found in the œsophagus; it had penetrated the aorta. The stomach was distended with fluid blood.

In the following case, the hæmorrhage came from small vessels:—"An aged female", says Dr. Copland, in his *Dictionary* (art. *ŒSOPHAGUS*, page 912), "had been under my care for years, for disordered digestion, accompanied with psoriasis. A few days before death, she was attacked with symptoms of œsophagitis and pharyngitis, attended by a constant hacking cough, and great depression of strength. On the eighth or ninth day of the attack, sudden and profuse hæmorrhage from the throat occurred, without any effort: death followed. The stomach contained a pint and a half of blood, partly fluid, and partly coagulated; and the mucous membrane was softened. The pharynx was of a dark colour, with purple coloured patches. In the upper third of the œsophagus, towards its anterior, on the left side, an irregular ulcer existed; it had destroyed the mucous and submucous coats, and in some parts the muscular. The parts around the ulcer were soft, tumid, and of

a purple hue. The bottom of the ulcer was red and vascular. Hæmorrhage had occurred from erosion of the small vessels."

CASE III. ULCERATION OF THE ŒSOPHAGUS PERFORATING THE PERICARDIUM. F., aged 25,* a servant, entered St. Mary's Hospital, under Dr. Chambers, January 23rd, 1852. Her face was anxious and pale; her conformation good; yet she was weak and reduced. She menstruated regularly. Three months back, she began to suffer from nausea, and to vomit frequently after meals. At the end of a month, difficulty in swallowing manifested itself, which had increased, with an aching, digging pain between the shoulders, and occasionally pain in the epigastrium. A piece of dry bread, on being swallowed, met with an obstruction near the top of the sternum. The pulse was 80; the tongue slightly furred; the skin cool; the bowels and urine natural. The back of the pharynx was slightly abraded. The matters vomited were frothy and acid. The respiratory murmur was deficient, though loud and coarse. In this state she continued up to the 2nd of March, when she had constant cough. The next morning, she was found pulseless, with livid lips and face. She died soon afterwards.

The pericardium was found distended; and, on puncturing it, air made its escape, followed by a thin, yellow, sour-smelling fluid. The œsophagus, from the bifurcation of the trachea to within half an inch of the diaphragm, was, in its whole circumference, the seat of ulceration. An opening communicated with the pericardium; and a little lower down was another, which opened into a small ulcerated cavity, at the root of the lung. The stomach was placed in a vertical direction; its pyloric extremity being situated an inch below the superior spinous process of the ilium.

ULCERATION OF THE ŒSOPHAGUS TAKING PLACE FROM WITHOUT.

CASE I. FIBROUS TUMOUR ATTACHED TO THE ARCH OF THE AORTA.† M., aged 68, robust, an agricultural labourer, had suffered for three months from difficulty in swallowing, with severe pain, which compelled him to return that which he had taken. This difficulty was greater with solids than with fluids. He had a constant sense of constriction at the upper third of the sternum; here the obstruction to swallowing existed, and here pain was excited. He had no fever nor cough. By a milk diet, he was much restored. At the expiration of two months, he again returned, with hectic, cough, and purulent expectoration. For some days, the deglutition had been quite easy. He sank in the course of a few days.

Adhering to the arch of the aorta, a fibrous tumour, impregnated with pus, was found, which pressed on the œsophagus. The œsophagus, for two fingers' breadth at this point, was quite destroyed, except a very thin layer. The lungs were filled with grumous and ichorous matter.

CASE II. ENLARGEMENT OF THE THYROID GLAND: ULCER: PERFORATION OF THE TRACHEA. F., aged 51,‡ from her youth had difficulty in deglutition, from some obstruction in the neck, rendering the introduction of an instrument necessary at times. The difficulty now became so great that fluids and sopped bread only could be made to descend. Solids did not produce pain; their descent was simply impossible. The thyroid, and the glands of the right side of the neck, were swollen and hard. Remedial measures had no influence on the affection. Low fever set in, accompanied with œdema. Viscid fluid flowed constantly from the mouth. A troublesome cough manifested itself; it was first dry, then with sanguine foetid expectoration, and accompanied with great anxiety in the chest. At last, fluids, when taken, excited severe coughing, and she soon sank.

The glands on the right side of the neck were hard, and of the size of walnuts, closely adhering to the internal

jugular vein. On section, they were found to contain a soft granular substance. The thyroid was hard and tuberculated, and at one point it had pressed on the œsophagus, and narrowed its diameter. Above this point, the œsophagus was considerably dilated; it was livid in colour, and its tissue was soft and spongy. On its being cut, foetid sanguinous fluid issued, like that expectorated during life. Several ulcers existed; and at the lower part of the cricoid cartilage was one which communicated with the trachea.

ABSCESSSES OF THE OESOPHAGUS RESULTING FROM OR ENDING IN ULCERATION.

CASE I. M., aged 66,* of robust health, contracted a severe cold, with inflammation of the throat. Deglutition became difficult, and soon impossible. This state was attended with fever. When seen seventeen days from the commencement of the attack, there was but slight redness of the throat. The lower part of the pharynx, although not swollen, was very tender on pressure. The food was rejected, mixed with much slimy mucus. Bleeding, leeches, and calomel, produced no favourable effect. A little pus mixed with blood was hawked up; but this gave no relief to the symptoms. He began to cough up a large quantity of foetid pus, and sank twenty-four days from the commencement of the attack.

The œsophagus was found to contain much foetid pus, which oozed through an ulcerated opening, communicating with an abscess behind it and the lower part of the pharynx.

CASE II. A lady,† while suckling her first child, began to complain of obtuse pain between the shoulders and in the præcordia, and at last of cardialgia, with pain of a like character in swallowing. At times she rejected her food, with viscid mucus, the moment it reached the point where the pain existed. She was advised to discontinue suckling, and take bland emetics and purgatives. By these measures, much benefit was produced; so that she was enabled to get down a little very finely chopped meat. The improvement, however, was only temporary. Various other remedies were had recourse to, but to no purpose. She had at last vomiting of thin blood with the food. Slow fever followed, and soon afterwards she died.

Opposite the fifth or sixth dorsal vertebra, an abscess existed. The œsophagus was ulcerated, and the posterior part of the lung was sphacelated. The liver was soft, and the pelvis of the kidney contained pus.

CASE III. A man,‡ whose health until February of 1849 had been good, began to feel pain in the middle of the sternum on swallowing. This increased, and very soon became constant; deglutition of solids became impossible, and that of fluids was attended with more and more difficulty, and at last they were quite arrested. Some weeks after this, while making an effort to swallow some fluid, some pus and blood was brought up: this occurred again, and the deglutition of fluids became possible. He went on improving, and was soon able to swallow solids. In September, in consequence of taking cold, the difficulty in swallowing returned; and he had a sensation as if a sore spot existed in the œsophagus. The appetite failed, and he lost both flesh and strength. The swallowing of fluids soon became difficult; and, by the 28th of October, the attempt to swallow the smallest quantity excited sudden and severe cough. He sank on the 3rd of November.

The glands of the œsophagus were hard and enlarged. In the canal, an inch below the division of the trachea, an opening, of the size of a fourpenny piece, existed, which communicated with the left bronchus. The pleura on this side was adherent.

CASE IV. ABSCESS IN THE WALLS OF THE OESOPHAGUS, FOLLOWED BY ULCERATION. A child, between 12 and 13,§ whose health had been previously good, was taken in the

commencement of December 1807 with a severe cough, and great difficulty of breathing on the slightest exertion. To these, fever of an irregular character was soon added. In the beginning of February, the cough was constant, and the fever doubled in intensity. On the 3rd, the oppression and suffocative sensation were very severe; the pulse was very rapid; the expectoration glairy and transparent. No trace of opacity was observed until the end of the month, when it became opaque and purulent. The epigastrium was rather tender, and the abdomen often voluminous. The emaciation was severe and increasing; the abdomen became hard, and the fever constant; and, for three days before death, she vomited incessantly black matter, like that from cancer of the stomach. She died on the 6th of March.

The œsophagus contained black fluid; on its posterior and lateral aspects, it was pierced by two round ulcerated openings; these communicated with a sac, the outer wall of which was formed by the external covering of the œsophagus. This sac adhered to the inferior, posterior, and interval of the right lung, and below rested on the liver. It still contained some of the fluid like that in the œsophagus, and which had been vomited. The lung of this side was small, and contained several small tubercles. Several of the bronchial glands, below the bifurcation of the trachea, were of the size of pigeons' eggs, but not in a state of supuration. The great omentum was covered with tubercles.

CASE V. ULCER FOLLOWED BY ABSCESS IN THE WALLS OF THE OESOPHAGUS. A F., aged 52,* delicate, became in the winter of 1782 much troubled with dyspepsia, and when seen in the following February (1783), she had nausea, with frequent retching and difficulty in swallowing; by emetics and purging, considerable relief. On the 28th, the difficulty of swallowing returned with a sense of suffocative constriction in the throat; this was somewhat relieved by foetid julep. By the 26th of March, the pain and difficulty in swallowing was very severe, all taken being returned. Two ounces of quicksilver, swallowed, seemed to clear the passage for a short time. The same night she had a rigor, and she retched all food even after it had entered the stomach; the pulse was small and quick. If she took a large quantity of fluid, it seemed to make its way by its weight into the stomach, but a small quantity was rejected before reaching it. Porter agreed better with her than anything else. She now became better for some weeks; but on the 25th of April she had another attack. After swallowing the same amount of mercury as before, with other remedies, she again passed a month of comparative ease. At the end of this time she had another attack, followed by profuse discharge of saliva from the mouth, to the amount of a pint and a half in twenty-four hours. She became much reduced, and had constant pain in the side; her stools contained at times a slimy matter, after the discharge of which, the flow of saliva from the mouth was much lessened. Some calomel was given without any increase of saliva. In July, rigors appeared, and the pain in side increased much in severity; the pulse sank, and she vomited all food; constant fever with severe thirst were also present. Broth clysters were given; she at last sank into a state of stupor, and died at the end of twenty-four hours.

The *post mortem* examination was made by John Hunter. In the walls of the œsophagus, below the division of the trachea, an abscess existed, communicating with the canal, which was ulcerated to the extent of four inches. The stomach was contracted, and contained some green fluid like bile.

ULCERATION OF THE OESOPHAGUS WITH PERFORATION OF THE TRACHEA, BRONCHI, OR AFFECTIONS OF THE LUNGS.

CASE I. ULCER OF THE OESOPHAGUS: PERFORATION OF THE TRACHEA: ABSCESS IN RIGHT LUNG. M., aged 50,† entered St. Thomas's Hospital in February 1781. He had been suffering for a few days from difficulty in swallowing: the

§ Halle, *Bibliothèque Médicale*, tome xx.

* Garthshore, *Medical Communications*, vol. i.

† Keir, in *Medical Communications*, vol. i.

food met with some obstruction near the middle of the sternum, and in less than a minute was rejected; and with fluids, severe cough was excited. The breathing was difficult, and he had had cough for some months duration, with copious expectoration of pus; the breath was foetid; he had frequent shivering fits; the pulse was strong and hard; he was bled and blistered, but he sank ten days from the commencement of the difficulty in swallowing.

In the upper part of the right lung a large cavity existed: it had destroyed the substance of the œsophagus, from the first to the third or fourth dorsal vertebra. An opening existed between the œsophagus and trachea, half an inch in size. The œsophagus, stomach, and trachea all contained pus.

CASE II. ULCERATION OF THE ŒSOPHAGUS COMMUNICATING WITH AN ABSCESS IN THE RIGHT LUNG. M., aged 58,* much exposed to sudden variations of temperature, and in the habit of drinking largely of spirits, although not to intoxication. Until he reached the age of 55 his health was good; he then became subject to a troublesome cough with mucous expectoration tinged with blood, and the pulse was full and hard. Blood was taken; cough mixture was given, and he was ordered to abstain from drink. Pain in the præcordia soon after came on when swallowing solid food, and increased in severity; the cough also returned. Various remedies were given, and at last mercury; this was followed by great benefit, and he soon was able to swallow with ease, and for a year he continued well. The cough then returned, attended with a sense of uneasiness and pain in the right side; the pulse was full and hard; the bowels constipated; the appetite gone. Leeches and laxatives were used; the last produced much relief. Difficult deglutition soon manifested itself; the food was rejected mixed with mucus, and even fluids soon ceased to pass. The exhibition of mercury was now unattended with any benefit, and he gradually sank.

The œsophagus, in the lower part, for four fingers breadth in extent, was hardened and in close connexion with the right lung; in the upper part it was much diluted and presented a great number of large mucous glands. The thickened part presented an opening communicating with a cavity in the right lung, which would admit the passage of the little finger.

CASE III. ULCERATION OF THE ŒSOPHAGUS WITH PERFORATION COMMUNICATING WITH A CAVITY IN THE RIGHT LUNG. A man† was severely squeezed in the neck by one of his comrades. For some days after, he had slight difficulty in swallowing; this gradually increased, and at the end of four months solids would not descend: at this time he took cold, and his voice became affected. On his admission into the hospital, fluids only would pass, and these only with very great precautions, otherwise cough was excited and they were returned. A bougie was arrested opposite the first ring of the trachea. He had frequent cough, with a copious expectoration, like the little round masses met with in chronic laryngitis. The respiratory sounds were feeble on both sides, yet no positive disease could be said to exist. He had no fever; his appetite was good; he had not lost much flesh, although his strength was reduced. Milk was his sole nourishment. A slight febrile indication soon afterwards set in; he had constant headache, the voice became nearly extinct, and the emaciation increased. Three days before death he had delirium; the fever doubled, with great agitation; the next day the agitation was less, but the delirium continued; the pulse was soft and compressible; in the evening it became small and intermittent, and the face pinched, and he sank the next morning at 5 A.M.

Serum existed under the arachnoid, but none in the ventricles; the veins of the surface were gorged, and the substance of the brain was soft but not discoloured. The œsophagus was narrowed so as scarcely to admit a female catheter. The obstruction was two and a third inches in length, and formed of soft fungoid-like vegetations; the mucous membrane was destroyed. In the centre of this ulcer two openings existed

of nearly the same size, capable of admitting a female catheter, separated from each other by a thin layer of membrane. These openings ended in a canal, large at its commencement, which ended in an excavation the size of a hen's egg in the upper part of right lung, and which contained a little purulent fluid. This cavity was not lined by a false membrane; the surrounding tissue was infiltrated, and several small bronchial tubes opened into it. The right lung was adherent and increased in density from capillary bronchitis, the left with sanguinous infiltration, in the superior lobe: in the inferior, three black cysts of the size of nuts existed. The larynx and trachea presented no change. The liver was gorged, and contained five or six pea-like, grey bodies. The kidneys were also gorged.

CASE IV. ULCERATION OF THE ŒSOPHAGUS, PERFORATION OF TRACHEA, AND ABSCESS IN THE RIGHT LUNG. M., aged 54;* health good. In December 1821, his appetite began to fail; he had flatulence and heartburn, with pain and uneasiness after eating, accompanied with spitting of frothy mucus. In the following January, he experienced a difficulty near the stomach in swallowing food. This symptom gave him very little trouble until May, when it became severe; some kinds of food exciting it more than others, large quantities of fluid being necessary to make it descend. Ropy mucus was also discharged by retching from the gullet. He began now to suffer from an uneasy sensation in the upper part of the right side of the chest, extending into the axilla. A probang passed with ease into the stomach, but it was followed by a great increase of pain in the præcordia and in the chest. By the 24th of July, he had lost much flesh, and his pulse had become quick. On the 1st of August, after more than usual fatigue from business, he had in the night a febrile attack, with severe pain in the upper part of the right side of the chest, shooting to the back. No cough. Pulse 100, full. He was bled and blistered, and had antiphlogistic diet. On the 6th, cough manifested itself, particularly on taking food, but seldom at any other time, except at night, when it was very troublesome, and attended with a little frothy mucous expectoration. He seemed, up to the 24th, to make some slight improvement; but on that day he had a severe shivering fit, followed by fever, and great increase of the pain in the chest. Deglutition was at times very difficult, and the cough most distressing. On the 26th, nothing would pass; cough very severe; pulse 112, strong. An elastic tube was introduced, but it would not pass lower than the upper part of the sternum. A catheter descended somewhat lower. Some beef-tea was injected through it, but it produced violent cough and threatening suffocation. In the night, the power of swallowing returned, and he took without difficulty a pint of chocolate. The cough continued very troublesome on taking liquids, and most offensive purulent matter was expectorated. On the 28th, he was sometimes able to swallow, at others not; little of whatever was taken reaching the stomach. In the evening, he discharged a portion of slough by expectoration. Pulse 96; skin hot and dry. There was but little alteration in the symptoms up to the 1st of September, when he sank. He had lost flesh; his tongue had become dry; the purulent expectoration had diminished, but he passed it in his motions; but the retching and sickness continued very severe, yet nothing was brought up. During the last twenty-four hours of life, he had been able to swallow; and even brandy and water could be taken without exciting cough.

The right lung, in its upper and posterior part, contained a large abscess; the œsophagus and trachea forming a portion of its walls. The œsophagus was destroyed in one-half of its circumference, to the extent of four inches in length. An opening existed in the trachea, from half an inch above the bifurcation to the same distance below it, on the right bronchus. The tissue of the lung was condensed around the abscess. In the œsophagus, a line of tubercles, of the size of split peas, existed under the mucous membrane; below this, near the cardia, a large

* Blenlaud, *Icones Anat. Pathologicae*.

† Vigla, in *Archives Générales de Médecine*, 1846.

* Hay, in *Transact. of Medico-Chir. Society of Edin.*, 1834.

tubercle was situated on the external part of the canal. At the point of junction of the stomach and œsophagus, an irregular mass of hardened glands existed, which compressed the opening, yet admitted the passage of the little finger with ease. The other viscera were healthy. During the latter period of life, he was nourished by beef-tea enemata.

CASE V. ULCERS OF THE ŒSOPHAGUS, COMMUNICATING WITH CAVITIES IN THE RIGHT LUNG. F., aged 12,* entered the Hôpital des Enfants, September 12th, 1840. She had had scarlet-fever in July; the eruption disappeared, yet the fever increased, and was attended with pain in the right breast. She soon began to expectorate purulent foetid matter. She had foetid breath, with vomiting and retching, and great emaciation. To these symptoms, after her admission, diarrhœa was joined. The stethoscope gave indications of a cavity in the right lung. On the 16th, after coughing, she brought up ten drachms of venous spumous blood, with a gangrenous smell: the same occurred on the following day. She sank on the 21st, after suffering from severe pain in the right side of the chest.

In the median line of the œsophagus, near its centre, four ulcerated perforations existed; the superior one was longest: they communicated with a cavity in the right lung, capable of holding a small apple; this again communicated with a second, of the size of a plum, in the superior part of the lung; and this one communicated with another half its size. The first cavity was lined with a false membrane, and both it and the second contained flakes of grey pulmonary substance, with foetid grumous fluid, of a gangrenous odour. Into the second a bronchial tube opened; it, as also did the smaller cavity, contained some dark clots of blood, mixed with caseous matter. Other cavities, but isolated, existed, containing dark gangrenous diffuent matter, and, in other parts, tuberculous infiltration. The bronchial glands were large and black.

CASE VI. ULCERATION OF THE ŒSOPHAGUS, COMMUNICATING WITH ABSCESS IN THE RIGHT LUNG, WITH PERFORATION OF THE PLEURA. M., aged 34,† had good health up to January 1833, when he began to vomit his food a quarter of an hour after it had been taken, if it consisted of solids: this was accompanied by pain in the upper part of the epigastrium. Some pills, which he obtained from a medical man, so far relieved him, that the affection ceased to trouble him, except when he took solids. On the 27th of June, he entered the Klinik at Bonn. His aspect was somewhat yellow and emaciated; tongue white, and mouth overflowing with mucus; and he complained of a kind of sticking pain in the upper part of the epigastrium, extending to the sides. Respiration was noisy in the subscapular region, with dullness on percussion; but he had no cough. Swallowing was followed by constriction in the breast, and a sensation as if some obstacle existed in the dorsal region to the descent of the morsel, which did not make its way into the stomach until eructations and discharge of water had taken place. A probang was introduced to the extent of nine inches, and, on being withdrawn, the sponge was found covered with viscid mucus. Hunger was very great; the thirst moderate; the bowels constipated; and the urine yellow with sediment. The motions obtained by laxatives were black. The pulse and skin were natural. Leeches, belladonna, clysters, and milk diet were used. On the 30th, he complained of severe pain in the right breast. On the 14th of July, the belladonna affected his throat and eyes; and on the 17th he passed a bad night, from a troublesome cough. Dullness on percussion, and deficiency of respiration, on the right side of the chest were observed. On the 25th, the pain had not increased, but it had extended more towards the sternum. On the 7th of August, a sound was introduced, and produced severe pain in the vicinity of the cardiac orifice of the stomach; and the cough now excited

retching. On the 12th, the pain and cough were very severe; and on the 14th he had diarrhœa, with pain in the upper part of the abdomen, increased by pressure. The urine was scanty. On the 15th, the cough was worse; the urine scanty, and dark red; the pulse 100, hard and small; the pain in the chest was severe. Pleuritic symptoms being evident, six ounces of blood were taken by cupping, but without relief. On the 17th, he had muco-purulent expectoration, frequent retching, and severe dyspnœa. Pulse 120, small. On the 21st, the pain and dyspnœa were much increased, with ægophony in the right mammary region. Death took place on the 25th.

The œsophagus was ulcerated from opposite the fourth dorsal vertebra to near the cardiac orifice of the stomach. In its upper part, an opening, two inches in diameter, communicated with a cavity in the lower lobe of the right lung, six inches long and four broad, containing black foetid fluid: this again opened into the right pleura. The pleura was adherent, and contained about four pounds of yellowish white fluid, of a sour foetid smell, with oil-globules and pieces of fat floating in it. The upper lobe was infiltrated with red serum; the lower part of the middle lobe crepitant, but would not float in water; the lower, in the vicinity of the cavity, was soft and infiltrated; it also contained a small cavity, of the size of a nut, filled with yellow fluid. The pericardium contained five or six ounces of fluid; the heart was normal. The cardiac opening of the stomach was quite free; but the mucous membrane was swollen, with some traces of ulceration. The liver was very large, extending to the left side.

CASE VII. M., aged 12, of a somewhat scrofulous habit, while playing with some schoolfellows, swallowed a piece of slate-pencil, about half the length of the finger, with a piece of thin string attached to its centre. Some efforts were made to extract it by himself; but these not succeeding, they took him to a surgeon, who, after making an attempt to withdraw it, pushed it with an instrument into the stomach. Severe pain was excited, and some retching of mucus and blood took place. He ate his dinner without much difficulty, after the first two or three mouthfuls; and he had a slight sensation of soreness, which, for the next seven or eight days, continued much in the same state. The swallowing was rather better; but he had great difficulty in swallowing dry bread, which seemed to meet with some obstruction near the lower part of the breast-bone: it was deep seated, and attended with a kind of agonizing sensation in the spine. In this state, the first fifteen days after the accident were passed. He then began to complain of a pain in the right side of the chest, and to suffer from slight feverishness, accompanied by an unusual amount of thirst. The pain in swallowing also increased, and he had also slight nausea, with a tendency to retch. He now fell under my notice. There was absence of respiratory murmur at the point where pain was complained of; but this was more distinct posteriorly than anteriorly; and here, both above and below the point, some crepitation could be detected. He had also slight cough, with dark expectoration. The pulse was quick and small. Leeches were applied to the seat of pain; milk diet, and small doses of calomel and opium were ordered. For a week after, he seemed to improve slightly; the pain was rather less; the cough was not quite so severe; and the fever was somewhat diminished; but the thirst continued. At the end of this time, he had a distinct rigor one evening; and, four days after, he began to expectorate foetid purulent matter. This increased in quantity; the cough became more distressing; and the voice was affected. He had now constant sense of chilliness; his cheeks were livid, his eyes sunken and brilliant. A cavity was detected in the right lung. When pus appeared, the pain in swallowing increased; and fluid, if taken too rapidly, excited retching and vomiting. A constant sense of distressing constriction existed in the upper part of the throat. Ten days before death, after drinking a large teacupful of fluid to allay the thirst, severe vomiting was excited, and foetid pus was brought up. From this moment, fluids taken seemed to pass partly into the chest, and partly into the stomach;

* Bordet, Sur la Gangrène Pulmonaire, Arch. Gén. de Méd., 1843.

† Hecking, Diss. de l'œrfor. Œs. Ulcerat. Bonnæ, 1834, in Albers' Atlas der Pathologischen Anatomie.

but they did not immediately excite cough. His bowels became relaxed; his stomach very irritable; and he had tenderness in the epigastric region; and he died.

In the lower third of the œsophagus, an ulcer, three-quarters of an inch in length, and half an inch broad, existed. The mucous membrane, to the extent of three-quarters of an inch in circumference, was dark, and easily raised; the sub-mucous and muscular tissues were softened. From the centre of the ulcer, an opening, which would just admit the point of the little finger, passed into an abscess the size of a moderate sized orange, the walls of which, formed by the substance of the lung, were soft, and infiltrated with pus. The mucous membrane of the lower part of the œsophagus was vascular and swollen; that of the stomach was the same; and that of the small and large intestines was highly vascular in parts. In the liver, several small specks of pus existed, surrounded by vascularity. The kidneys were red and vascular; in the pelvis of the right one, a trace of pus existed. In the upper lobe of the right lung, some tubercles existed, in a softened state; the left lung was highly congested; and here and there some red nodules existed, varying in size from a pea to a walnut, as if from deposit of pus.

CASE VIII. ULCERATION OF THE ŒSOPHAGUS: PERFORATION OF THE TRACHEA: GASTRITIS, AND COLONITIS. M., aged 55,* entered the hospital in June. Some weeks before, when tipsy, he had fallen against some sharp body. This was followed by pain in the upper part of the right side of the thorax, and difficulty in swallowing solids. Leeches and blisters removed the pain, but the difficulty in swallowing remained. A small tube was passed down into the stomach with some difficulty, from meeting with some resistance in the upper part of the sternum. On withdrawal, its orifice was found filled with puriform mucus mixed with blood. He left the hospital, and during the next two months the dysphagia increased, and he was reduced to live on milk with bread reduced to pulp. At the end of August he re-entered. Two attempts were made to pass a catheter, but without success; but a third succeeded. Some solution of nitrate of silver was introduced on a sponge attached to a piece of wire. Cough soon came on, with hawking up of glairy pus mixed with blood. On the 25th of November, in a fit of coughing, he brought up what was supposed to be a piece of slough; and from this moment no fluid could be introduced. An attempt was made to pass a catheter, but it failed. On injecting a little water through it into the gullet, it was rejected, and severe cough was excited, with expectoration of bloody mucus; and any attempt to swallow was followed with the same results. On the 28th, a tube was passed with much difficulty twice: after this it was passed frequently. Symptoms of gastritis set in, and he sank on the 14th of December. The œsophagus, above the bifurcation of the trachea, was ulcerated and thickened to the extent of four inches, and an opening the size of a shilling existed midway between the larynx and the lower part of the trachea. Below this point, the canal was red. The mucous membrane of the stomach and the colon, as low as the sigmoid flexure, was inflamed. The mucous membrane of the trachea, both above and below the opening, was highly vascular, and covered with purulent mucus. Some traces of recent inflammation existed in the right pleura.

CASE IX. ULCER OF THE ŒSOPHAGUS, COMMUNICATING WITH ABSCESS, AND WITH THE TRACHEA. M., aged 60,† a baker, for the last ten years much addicted to spirits, became in the course of August 1833 subject to an attack of catarrh, which was followed by difficulty in swallowing. Food seemed to meet with some obstruction, and this particularly if he swallowed it without being well masticated; considerable pain was also produced. On the 1st of September, the food began to be returned, mixed with a large quantity of mucus, and he was much troubled with a

dry cough; particularly on swallowing fluids, which, however, met with no difficulty or obstruction. The bowels were constipated; and the pulse was varying, at times full, at others small. Tartar emetic was applied externally, and mercury given internally, much relief following. In the middle of October, the pain and cough became much worse, from a piece of potato of the size of a pea being arrested. At the end of twenty-four hours it was got rid of; and by the end of the month he was enabled to swallow without much difficulty. But on the 9th of November the difficulty in swallowing returned; severe cough set in some moments after food had been swallowed; and the food was also returned mixed with slimy mucus. The next day he had mucous expectoration with the cough; and towards the end of the month, he never coughed without bringing up particles of food taken some time before. His health began to sink. Three days before death, which took place on the 20th of December, all he attempted to swallow was returned with severe coughing.

In the œsophagus an ulcer existed, three inches long and two inches broad: in the centre of it was an opening capable of admitting a bean, communicating with an abscess, which opened also into the trachea by two openings of about the size of beans; the superior one an inch above the bifurcation, the other four lines below, in the right bronchus.

CASE X. ULCERATION OF THE ŒSOPHAGUS, WITH PERFORATION OF THE RIGHT BRONCHUS. M., aged 3,* entered the Hôpital des Enfants, May 22, 1823. He had suffered from cough for six months. Of late it had been of a convulsive character, but was now somewhat better: he had also been subject to diarrhœa, and was now suffering from it. He had sweats, anorexia, and great difficulty in swallowing fluids, from its producing severe cough. There was mucous râle in the post part on the right side of the thorax, and the voice was hoarse. The diarrhœa again stopped; but it returned again on the 25th, with great increase of the cough, severe thirst, and death.

In the œsophagus, a quarter of an inch below the bifurcation of the trachea, an ulcerated opening two lines in diameter existed, communicating with the right bronchus.

CASE XI. ULCERATION OF THE ŒSOPHAGUS, WITH PERFORATION OF THE RIGHT BRONCHUS. M., aged 63,† since youth addicted to drink, swallowed in a fit of drunkenness some pieces of glass. Some months after, he began to complain of a pain in the breast, which continued for some time, and then became more severe, and of a burning character, attended with difficulty in swallowing, from the food meeting with some obstruction near the ensiform cartilage. Four months later, he began to suffer from cough; and afterwards the swallowing of fluids or solids excited it, and they were returned mixed with slimy mucus. The breath was unaffected. He died in one of the fits of coughing.

In the œsophagus, an ulcer the size of a five-shilling piece existed; and from it an opening of the size of a four-penny piece passed to the right bronchus.

ULCERATION DEPENDING ON CHRONIC INFLAMMATION OF THE CANAL.

CASE I. CHRONIC INFLAMMATION: ULCER: DESTRUCTION OF THE THYROID GLAND, AND PERFORATION OF THE LARYNX. A female, aged 60,‡ from a cold, became subject to difficulty in swallowing, which remained much in the same state for fifteen months; then pain occurred, with hawking up of a viscid substance. In spite of treatment, the disease gained ground; her voice became sharp and whistling, and the expectoration tinged with blood; at last it was only with the greatest difficulty and pain, and in a certain position, that fluids could be made to descend. The pain was referred to a spot a little below the thyroid cartilage. The fluid expectorated consisted first of altered blood with a peculiar foetid smell, and then of pure pus. She had constant burning thirst, and great emaciation: low fever at last set in, accompanied with delirium, which was followed by death.

* Lindesay, Transactions of the Medical and Physical Society of Calcutta, vol. viii.

† Hecking, Diss. de Perfor. Œs. Ulcerat., Bonnæ, 1834, in Albers' Atlas der Pathologischen Anatomie.

* Leblond, Thèse de Paris, 1822. No. 196.

† Albers, Atlas der Pathologischen Anatomie.

‡ Taranget, Jour. de Méd., Chir., et Pharmacie, 1786.

The œsophagus was in a state of gangrene from the commencement of the trachea downwards, for four fingers' breadth; below this the canal was considerably narrowed from chronic inflammation. The thyroid gland was quite destroyed; and communications existed between the pharynx and larynx.

CASE II. CHRONIC INFLAMMATION: ULCER. A female* had for the last ten years of life suffered from difficulty in swallowing, and very frequently during the last two years food was very apt to lodge, and could only be got rid of by retching. In September 1744 she was unable to swallow solids, and soon afterwards had the same difficulty with liquids. The throat seemed paler than usual: she had constant dryness, but no fixed pain, discharge from the mouth, or fœtor of breath. For six weeks before her death she was nourished entirely by broth clysters.

The upper part of the œsophagus, for three inches of its length, was converted into a tough brown viscid substance: below this point the canal was narrowed. The thyroid gland was enlarged.

CASE III. CHRONIC INFLAMMATION: ULCERATION BELOW THE STRICTURE. F., aged 36,† within twelve months before her death began to suffer from dysphagia, which gradually increased. She took mercury without benefit. When seen, ten months from the commencement of the affection, no solids would pass; fluids passed only with great difficulty and severe pain, which extended to the Eustachian tubes. An attempt was made to pass a bougie, but it was arrested opposite the cricoid cartilage, a smaller one was then tried and passed, but the irritation produced was so great, that it could not be introduced again. Great difficulty was experienced in hawking up the phlegm, and at last this became impossible. For six days before her death, nothing entered the stomach.

Behind the cricoid cartilage a contraction of the canal existed, nearly obliterating it; half an inch below, two spots of ulceration existed. The thyroid and lymphatic glands were enlarged: this had taken place on the exhibition of the mercury.

CASE IV. CONGENITAL DYSPHAGIA: CHRONIC INFLAMMATION: ULCER BELOW THE STRICTURE COMMUNICATING WITH THE LUNGS. A lady, aged 59,‡ had been subject since infancy to a remarkable difficulty in swallowing. For the last thirteen years it had been very troublesome; and if the food was not well masticated before being swallowed, it became arrested and spasm was produced. Eight months before death, she was seized with pain a little above the pit of the stomach and a sense of chilliness in the back: these sensations left her, but returned at the end of a month, and continued. The food, when swallowed, passed down to the seat of the pain, which seemed to exist close to the orifice of the stomach. The passage of the first morsel was attended with severe agony, but after the second it was less. In addition to the pain, she had constant heartburn, and violent retching; these symptoms increased much in severity during the last six weeks of life, and she spat up a quart of mucus a day, and when the food was arrested, it returned mixed with mucus. A short time before death, an aphthous eruption appeared on the tongue, which spread to the fauces; and at the same time great difficulty in breathing set in.

The aphthæ were found, after death, not to have spread beyond the fauces. The œsophagus was contracted, but not thickened: behind the cricoid cartilage, an inch lower down, a second contraction existed: after this it became larger throughout, but was smaller than common. The canal, for three inches below the bifurcation of the trachea, was in a state of ulceration: from it two sinuses passed into the lungs, but did not communicate with any of the bronchi. The parts surrounding the ulceration were thickened and condensed.

CASE V. CHRONIC INFLAMMATION OF THE ŒSOPHAGUS: ABSCESS: ULCERATIONS COMMUNICATING WITH THE ŒSOPHAGUS AND LEFT BRONCHUS. A man,§ who had drank freely of

spirits, had suffered once from an affection of the stomach, and several times from *delirium tremens*, became, in January 1831, subject to pain in the chest and stomach. The last was relieved by remedies, but the other continued, and was followed by difficulty in swallowing, which increased to such an extent, that solids ceased to descend, and the same difficulty at last extended to fluids. He lost much flesh and strength. In July and August he suffered severely from hunger and thirst; his skin was hot; and fluids had ceased to enter the stomach. An attempt was made to pass a small tube, but without effect. On the 1st of September, he began to suffer from cough with purulent expectoration: and on swallowing fluids, they remained some time at the point where the obstruction existed; cough then came on, and they were rejected. This state continued up to time of death on the 24th. He was nourished by clysters.

From the middle of the œsophagus, as low as the orifice of the stomach, hard gristly thickening existed; and it was so narrowed, that the smallest catheter would not pass. Opposite the lower part of the trachea, a large mass of cellular tissue existed, which was in close connexion with the parts adjacent. This was found to be the sac of an abscess. Communications existed between it and the œsophagus and the left bronchus.

CASE VI. CHRONIC INFLAMMATION: ULCERATION. M., aged 42,* received, six months previously, a kick from a horse in the epigastric region, by which severe pain was excited. He soon after had an attack of ague. Difficult and painful deglutition set in after a cold, attended with burning sensation in the upper part of the epigastrium, and tenderness on pressure. No vomiting or nausea after eating existed, nor cough or difficulty in breathing. The appetite was good, and the bowels natural. A laxative on the 5th of June produced much relief. On the 7th, the difficulty in deglutition became much worse, and on the 11th, a dry cough set in with constriction of the throat, fetid odour from the mouth, and heartburn. The obstruction seemed to exist at two points, near the larynx and at the orifice of the stomach. On the 15th, the cough was worse, much viscid mucus being brought up. By the 22nd, the strength was much reduced: and fœtid pus was coughed up. He sank one month from this time. The obstruction at the upper part of the canal disappeared a fortnight before death.

The œsophagus opposite the fifth dorsal vertebra was so narrowed for an inch of its length, that a pen with difficulty could be made to pass; above this the canal was enlarged, and contained purulent ichorous fluid. The whole of this tract was of a livid grey hue and adherent to the trachea: the two canals seemed to have a common orifice. The lungs were not adherent, but they were filled with spumous serum and blood. No fluid was found in the pleural cavities.

Harrington Square, London, Sept. 1853.

ON DEGENERATIONS OF THE GLANDULAR STRUCTURE OF THE STOMACH.

By C. HANDFIELD JONES, M.B.Cantab., F.R.S., Assistant Physician to St. Mary's Hospital.

It is an ungrateful task for the pathological observer to have to add to the number of morbid changes, which, there is but too much reason to fear, are irremediable. From this unwelcome knowledge, however, one advantage, at least, results: that the mind of the practitioner is saved from that painful feeling of disappointment which naturally follows when we find remedies of no avail in cases where we trusted they might have been potent for good. It is at least some satisfaction, though a poor one, to know that our best-directed efforts to restore healthy action may fail, not because our measures were inappropriate to the case, but because the structure whose function we would restore had perished. Probably there is no organ in the body on whose

healthy condition so much of our comfort depends as the stomach, none, in consequence, whose ailments have been more studied and written upon; and yet it seems rather remarkable that hitherto we have had no careful investigation of the morbid changes which its mucous membrane (that most essential part of it) undergoes. No one has yet done for the stomach what Johnson, Simon, and Frerichs, not to mention others, have done for the kidney. And yet the mucous membrane of the stomach is a true gland structure, essentially different from that of the intestine; its follicles are not mere involucri of the surface, they possess a much higher function than that of merely secreting mucus. Examination of a vertical section of the healthy tissue shows that in the greater part of its extent it is made up of parallel tubes ranged side by side, and so close together that there are scarcely any interspaces discernible. These tubes are nearly of the same size as, and altogether very similar to, those of the kidney; the chief difference is, that they are more filled with epithelium, and do not exhibit a distinct central canal. They terminate as they reach the corium of the mucous membrane by blind extremities, which are often slightly bulged, and sometimes slightly branching. Above, they open into shallow fossulae, which are well represented in Bowman and Todd's *Physiology*, vol. ii, p. 193. These fossulae are lined by an epithelium consisting of columnar particles, while that which fills the tubes consists of nuclei imbedded in granulous matter, and very numerous large nucleated cells full of granulous contents. This gastric glandular epithelium differs from the renal in this important circumstance relative to the discharge of its function, that it does not remain, like the latter, attached to the basement membrane, the wall of the tube, but is thrown off and constitutes itself a part of the secretion. In the pyloric region, the fossulae are very much deeper, and the entering tubes much shorter; while low villi, containing single capillary loops, spring from the partition walls of the fossulae. In the other regions of the stomach there are no true villi, but a deceptive appearance is occasionally presented by papilloid masses of altered epithelium exuding from the tubes.

One morbid condition which is not uncommonly observed, is an atrophic state of the lower ends of the tubes and of their epithelium. The latter, then, consists of coarse granular matter, with a few stunted, starved-looking nuclei and cells which often contain oily molecules. The lower blind ends of the tubes are faintly marked, and sometimes are evidently tending to disintegrate; at the same time the interspaces between adjacent tubes seem wider, as if some had already disappeared. In some cases the epithelium is altered, containing no healthy cells, but filling up the tubes with a coarse granular matter, while they themselves are not atrophied.

A fatty change in the epithelium is not uncommon, and in some degree is scarcely to be regarded as of pathological import. The lower ends of the tubes in our domestic animals are often quite opaque from the presence of much oil in the epithelium: there is, however, in such instances, no indication of wasting or breaking up of the tubes. Sometimes the glandular tissue seems to undergo what may be called true fatty degeneration: the tubes lose much of their natural aspect, and become converted into cylindrical tracts of granular matter loaded with oil drops. When the epithelium is in a fatty state, the inner surface of the stomach will often be found to be of a dead dull white colour; and it is rather remarkable that sometimes the change is confined to patches of varying extent, perfectly circumscribed. This change in the colour of the stomach is noticed by Andral as the result of chronic gastritis.

Together with a varying degree of atrophic change in the tubes themselves, there is often observed a remarkable alteration of the submucous tissue, or rather of the areolar tissue which forms a kind of corium to the mucous membrane. On viewing a vertical section, masses of nuclear particles are seen heaped up among the fibres, where they come in contact with the blind ends of the glandular tubes; these increase and advance upwards between the tubes, and

occasion or coincide with their atrophy. The masses of nuclei are separate from each other, a certain space of healthy tissue intervening between them. The spots occupied by the nuclear deposits are sometimes depressed, so as to give rise to an appearance of open follicles. In an extreme instance the nuclear deposit has so increased as to cause almost a complete atrophy of the tubes, debris alone of which can then be discerned amid the altered intervening tissue. Vascular injection is by no means a constant accompaniment of this condition; and when it exists, it has not appeared to me at all clear that it was not of a passive kind. Together with the nuclei there is a certain quantity of granulous matter, which varies, however, in amount: it is not generally enough to conceal the nuclei.

Sometimes the exudation shows some tendency to the production of fibroid tissue, but I have never seen this developed in a very marked manner. Perhaps, however, contraction of the surrounding areolar tissue may have been the cause of the peculiar alteration observed in the following instance.

In a female, of thin and spare habit, who had been ailing two years, and who died of bronchitis with emphysema and dilatation of the heart; the liver was in a highly nutmeg state, and its Glissonian sheaths were considerably thickened; the kidneys were not healthy, and they contained reddish yellow pigment, the sign of former extravasations of blood. The mucous membrane of the stomach in the region adjoining the pylorus had a mammillated aspect, and was of a reddish brown colour. It was covered over with small, indistinct, sometimes whitish eminences, which were very apparent on a vertical section as whitish grain-like masses in the deeper parts of the mucous membrane. These masses consisted of tortuous tubes crowded and packed together, and filled with an epithelium consisting of small sized cell particles containing oily molecules, and of free nuclei imbedded in abundant granular matter. The basement tissue of the tubes was distinct in the masses, but could not be traced upwards to the mucous surface. In fact, the convoluted tubes seemed quite destitute of any outlet for their contents. The masses were separate from each other, and were closely girt by layers of fibroid tissue which seemed to compress them. In their intervals there was no trace of tubes. The epithelium of the surface preserved its usual columnar form.

I subjoin further details of the examination of some instances of the degenerative changes in the gastric mucous membrane above described.

A pallid, ill nourished female, aged 22, who had long suffered with epigastric uneasiness and bad digestion, died of phthisis and bronchitis. She had been fifty-one days in the hospital, and had undergone the operation for ruptured perinæum, which proved quite successful. The contents of the stomach were acid. Some portions of the mucous lining were of a dead white, and presented the appearance of numerous quasi-follicular orifices; the rest was of a faint reddish grey tint. There was no vascular injection anywhere. The white parts of the mucous membrane showed on a vertical section parallel rows of tubes filled especially at their deeper parts with oil laden cells of very perfect form and great consistence; these cells contained oil dots, opaque and black (but not drops), imbedded in much granulous matter. Besides the cells, the contents of the tubes consisted of free nuclei and granulous matter. The tubes were not broken up; but every here and there the row was interrupted, and there was left an empty looking space, which was occupied either by remains of tubes atrophied and containing merely a faint granulous matter, or by a mass of nuclei only. In one section the tubes existed only at the upper half or two-thirds of the vertical extent of the mucous membrane, while at the lower they were atrophied and replaced by a mass of nuclei. It was these interruptions in the continuity of the tubes which gave the appearance of follicular orifices. In the pale non-whity portions of the mucous membrane the epithelium was much less fatty.

A man, aged 63, died with empyema, the consequence of an accident which had fractured several ribs. The cornea

presented distinct arcus seniles. There was but slight fatty change of the muscular fibres of the left ventricle. The kidneys were not quite healthy; there were cysts on their surface. The inner surface of the stomach was of a pale colour, rather uneven; the mucous membrane to the eye was not much altered, but under the microscope the tubes were found to be extremely wasted, and in many parts quite lost, and replaced by a granular and fibrous tissue containing multitudes of ill shaped nuclear particles. In some parts there were groups of convolutions and bulgings of the tubes, stuffed with an opaque granulous and oily matter. The atrophy of the tubes was extremely marked. There was fibrinous deposit in the spleen.

A female, aged 19, died with syphilitic phagædena of the genitals. The stomach presented a natural aspect, with the exception of some slightly raised spots of the size of a pin's head in the vicinity of the pylorus. These seemed to be produced by accumulations of epithelium in the fossulæ. The tubes in this part were in a normal state. In the mid-region of the stomach the tubes were much wasted, those remaining only contained a granulous and oily matter.

In a middle-aged female, dying with scirrhus pylori, the stomach was found distended to some extent; its muscular coat was much hypertrophied; its mucous membrane apparently healthy. On closer examination, the lower ends of the tubes near the pylorus were seen to be aggregated into bunches, while in other parts they were very indistinct, evidently atrophied, and surrounded by intertubular exudation, consisting of nuclei and granulous matter. In one section, two large cysts were seen, full of a transparent fluid, and lined by a delicate vesicular epithelium. They lay in the substance of the mucous membrane. The kidneys were granular and cysted. There was considerable fibroid thickening of the capsule of the spleen, and some also of that of the liver.

A man, aged 51, addicted to drinking, and subject to gout, died with double pneumonia, pleurisy, and pericarditis, after five days' illness. The kidneys were healthy. The stomach appeared markedly mammillated in its mid-region; it was not injected. The tubes appeared pretty natural, but were obscured by an interstitial exudation, developing itself into nuclei and granulous or perhaps indistinct fibroid matter: at one part there was a large nodular accumulation, consisting solely of nuclei. From this mass, the nuclear deposit extended in smaller quantity among the tubes, and would, at a later period, have no doubt occasioned their atrophy. The mucous membrane of the fundus was red and softened; but its tubes were quite natural, and unobscured by any intervening exudation. The pyloric portion, like the cardiac, showed no trace of mammillation: there was, however, in this part very considerable intertubular fibroid formation, with infarction of the lower ends of the tubes by oily and granular matter; and gathering up of their lower parts into bunches. Many tubes in this part were also atrophied, so that a section no longer presented a continuous row.

In a female, aged 43, who died of uterine cancer, the mucous surface of the stomach was of a dead white colour throughout. The tubes were not wasted, but were filled with a very opaque fatty epithelium. In the mid-region, towards the greater curvature, there was a marked mammillated aspect; this very nearly disappeared after dissecting the mucous membrane from the submucous, and spreading it out. It was probably caused by some irregular contraction. The liver was excessively fatty.

A female, aged 87, died with universal jaundice; the femur was fractured by a fall some days before death. The liver was somewhat granular on the surface, and the Glissonian sheaths appeared somewhat thickened. The ductus communis choledochus was obstructed at its lower part by a soft mass of biliary pigment matter; the gall-bladder was hence enormously distended. The kidneys were wasted and granular. The stomach was very large; the mucous membrane was quite pale, but not manifestly unhealthy to the eye. Under the microscope, it was seen to be gravely altered; there was very little trace of tubes to be discovered even on

repeated examinations; here and there were some traces of them, but in by far the greater part of the tissue they had perished. Their place was occupied by a quantity of nuclear particles, granulous and some oily matter, and occasionally fat vesicles. The formation of nuclear particles had extended quite into the corium of the mucous membrane.

A man, aged 37, died with general peritonitis, after the recto-vesical operation, undertaken in consequence of the urethra being obliterated by stricture. The stomach appeared natural to the eye. In the middle and the splenic regions, the epithelium of the tubes consisted of small, stunted, atrophied particles, appearing more like empty vesicles than anything else; it was not fatty. In the pyloric third, the epithelium was not atrophied; large granular round and oval cells were present in the exuding contents of the tubes, besides free nuclei and granulous matter.

A stout man, aged 52, man, in apparent health, died with extravasation of blood within the cranium, after a blow. The mucous lining of the stomach had a dead white appearance, and seemed to be irregularly mammillated, or as if its surface was every here and there somewhat elevated. The epithelium of the tube was much atrophied; it consisted of stunted cells, granular matter, and ill developed nuclei. The tubes themselves were wasted in some degree; their deep ends were most affected, and lay imbedded in a stratum of granular matter, containing numerous nuclear particles, which infiltrated the areolar tissue. Acetic acid brought the intertubular nuclei more plainly into view.

I do not intend on this occasion to enter into any detailed examination of the causes and nature of the above changes; I can only state that I am not inclined to regard them as of inflammatory origin. They seem to us to belong much more nearly to the class of pure and simple degenerations, occurring as primary morbid phenomena, from the decay of vital power. Hyperæmia has not appeared to form any constant or necessary element of these textural changes. In the case of the nuclear formations, it is clear that there is intertubular exudation; but we have no evidence to show that it is the product of inflammatory action; I should rather consider that, owing to derangement of the natural assimilative power, the plasma, which should have formed healthy epithelium and other structures, was developed into these abnormal organizations. The morbid action seems to acknowledge a relation to cirrhosis of the liver, and to changes of the like kind. The newly formed fibroid tissue in cirrhosis is often loaded with nuclei, quite similar to those produced in the gastric masses. It is of course a matter of great difficulty to study satisfactorily the genesis of these morbid states; for, although there is strong ground for supposing that they exist in many of the multitudinous valetudinarians who are the commonest subjects of medical treatment; yet, as such individuals live on for years, and often die of some acute malady, there is seldom an opportunity of examining the organ affected while the change is in progress. To this subject I hope to devote much attention in future years, and shall be very thankful to any *confrère* who will furnish specimens and brief histories of the symptoms existing during life.

The practical results which the above investigation, as far as it has extended, supplies are:—1. That we may expect not unfrequently to meet with cases where the digestive power of the stomach is permanently weakened by the decay of more or less of its glandular structure. 2. That, in a still greater number of cases, the digestive power is weakened from an atrophy of the epithelium, which, it is conceivable, may, by judicious administration of light nourishing food, cod-liver oil, and gentle tonics, be reproduced in a more healthy state. 3. That we must be cautious in leeching or blistering epigastria for the removal of congestion, which may have no existence. The further our operation extends, the more do we become convinced that the most hopeless diseases with which we have to deal are those depending on essentially changes in the

rations of organs. Who would not rather have to deal with an acute pneumonia or pericarditis, than with a case of confirmed morbus Brightii? How often does our healing skill hang its head in hopeless foreboding when our diagnosis has revealed the existence of an organic lesion! This must of course often be; but how needful then does it become that we should be thoroughly aware of these degenerative tendencies, and exercise the utmost vigilance to anticipate and stay those destructive changes which we are unable to reverse.

1, Southwick Place, Hyde Park, London, Sep. 22nd, 1853.

BRAIN AND HEART DISEASE, WITH EXTRAORDINARY AND LONG CONTINUED REDUCTION IN THE FREQUENCY OF THE PULSE.

By ALEXANDER HENRY PATERSON, Esq.

CASE. T. S., aged 62, a merchant in Glasgow, came under my care on Sept. 25th, 1852. He was a short, very stout, and apparently healthy man, with a quick intelligent face and an energetic manner. In his previous habits he had been very active; he had travelled much for many years, and was very temperate. His previous health had been good, except that he had had frequent attacks of chronic bronchitis since the age of 18, and had within the last three years had three attacks of giddiness, caused by strong mental excitement, and producing momentary insensibility. On these occasions he fell to the ground, but immediately recovered himself, and had not either before or afterwards any headache, paralysis, or other symptom of brain disease.

In April 1852, Mr. S. was for the greater part of the day engaged in looking over a farm a few miles from home; and on his return, he endeavoured to overtake an omnibus. For this purpose he ran up a hill; and, having taken his seat, suffered much from difficulty of breathing and palpitation. These symptoms increased, and a few hours after his return home he was seen by a physician, and found to be dangerously ill, with congestion of the lungs and bronchitis. For many days he was unable to lie down; the pulse, which in health had been about sixty, now beat twenty-six times in the minute. Anasarca rapidly showed itself in the legs and thighs. The kidneys acted very imperfectly. The brain, and nervous system generally were unaffected.

The treatment was diuretic and expectorant; and at the end of a month the more urgent symptoms abated. The lungs continued very generally congested; the cough was troublesome, the expectoration copious, and the anasarca diminished. Mr. S. breathed easily when the shoulders were well supported, but could not lie flat down, and suffered very much from shortness of breath on making the least exertion, particularly in attempting to walk up stairs.

Mr. S. continued gradually to improve till September, when he was advised to winter in a milder climate; and for that purpose he came to Bowdon. His general appearance I have described. He at this time had no blueness of lips, or other indications of venous congestion. His extremities were cold unless well clothed; he could take exercise with pleasure on a perfectly level surface, but on attempting to walk up a slight ascent or a few stairs, his breathing became painfully hurried, and he said that he lost all power. The tongue was clean and healthy; the skin pale, otherwise normal; the appetite was tolerable, but he suffered much from flatulence. The kidneys acted freely. There was slight pitting at the ankles; the bowels were rather sluggish. He had had for some years a seton in the neck for the attacks of giddiness, and had for the last two months also had one in the left side. The pulse was 28, full, and pretty strong. Mr. S. suffered from no pain, and chiefly complained of disturbed nights. He had his shoulders supported by two or three pillows, but was apt to slip from them, and was then disturbed by difficulty of breathing and increased cough. He was also, frequently, when free from this,

unable to sleep on account of restlessness. The pulse had been as high as 32, but had not exceeded this since April.

A careful examination failed to detect any symptoms of cerebral or spinal disease. The lungs appeared generally dull, and mucous *râles* were heard all over them, particularly posteriorly. There was frequent cough, with very free expectoration of frothy mucus. The heart beat with increased impulse, but the stroke was undecided and the sounds confused and indistinct. The impression given by the physical signs was that there existed either pericardial effusion, or absence of the mitral valve; but the extreme stoutness of the patient and the *râles* in the chest obscured the diagnosis. Mr. S. had for some months been taking sarsaparilla with acetate of potash, and pilula ferri cum assafoetida; as well as some mild aperients. This plan of treatment was continued by me, with some occasional variations of the diuretics.

In the course of a few weeks, Mr. S. very decidedly improved. His pulse rose to 32. His cough was much relieved, and he could walk slowly up stairs without pain or much distress. The chief annoyance was from flatulence and restless nights. The diet was most carefully regulated, and medicine was nearly left off. On October 16, I was hastily sent for, and found Mr. S. apparently dying. The surface was cold; the face of a lead colour; the veins of the neck were very turgid; the breathing was stertorous; there was partial insensibility, and a feeble pulse of 28.

Mr. S., having on the previous day dined on Irish stew, had gone to bed in his usual health. Early in the morning, feeling some nausea, he rose for the purpose of taking a Seidlitz powder, and fell back in the state I have described. He shortly afterwards vomited; and, after taking some brandy and chloric ether, he gradually recovered his usual state.

My patient now had again an interval of tolerable health; he could walk two or three miles, wrote, read, and talked well, and for an hour or two at a time; and with increased care in his diet, he avoided a recurrence of such attacks.

In January 1853, Mr. S. had a few friends to dinner, and appeared in tolerable health. In the course of the evening, he went for a purpose of nature into the yard. While he was there, a servant quickly opened a back door. Being startled, he sprang a few steps backwards, and fell fainting to the ground. He was with difficulty carried to a sofa, and slowly recovered. About this time he complained of wandering pains in the head; and I thought his memory rather affected. After consulting his former medical attendant, we agreed to apply a blister to the nape of the neck, and give two grains of blue pill twice a day till the gums were slightly affected. The medicine was taken for nearly three weeks; it then produced the desired effect, and appeared to have caused some intermittence in the pulse. It was given up, and I did not again detect any head symptoms.

About the 12th of March, Mr. S. pointed out a pimple between his shoulders with a hardened base. This quickly enlarged, and became a carbuncle of the size of a cheese plate. The treatment consisted in occasional small doses of opium, wine and good diet, and stimulating poultices. I did not venture to make a free incision, fearing a dangerous return of the fainting and collapse. This carbuncle was followed by two more, smaller in size, but still giving extreme pain, and causing much thirst and restlessness. The pulse at this time varied; being on April 17th, at 10 A.M. 36, and at 5 P.M. 46. It was intermittent, particularly when sitting up in bed, and before taking food. I ventured on May 1st to lance the last carbuncle freely; and my patient bore the operation very well. He now began to recover his strength, his appetite being good. On the 4th of May, he got down stairs, and noticed his legs pitting, but there was no fluid above the knees. His urine was examined, and found to be natural in quantity and quality. His pulse was stronger (about 30), with occasional intermissions. On 23rd May he left Bowdon, and shortly afterwards returned to Scotland.

From Dr. Bell, of Glasgow, I have received the following account of the conclusion of this extraordinary case:

"Your old patient died at last (July 28) very suddenly. He was seized with a fit of dyspnoea, followed by the expectoration of several mouthfuls of blood. The difficulty of breathing rapidly increased; and he died, I think, about four hours after the commencement of the attack."

Dr. Bell also informs me, that a large tumour appeared some weeks before his death in the abdomen; it pressed on the rectum, and caused much pain, diarrhoea, etc. I very much regret to add that no *post mortem* examination could be obtained.

REMARKS. I have preferred to give an incomplete account of this case, to allowing all record of symptoms which appear so uncommon to be lost. An elderly man lives from April 1852 to July 1853, with a pulse averaging about 32; and at last dies, more apparently from the effect of some of the evident symptoms, than from the obscure cause of the disease. The physician, Dr. Bell, under whose care Mr. S. placed himself in May 1852, believes that he had suffered for some years from hypertrophy of the heart; that the run in April ruptured the *chorda tendinea* of the mitral valve; and that the alteration in the number of pulsations depended either on some effusion about the origin of the eighth pair of nerves, or on obscure brain disease. My own opinion coincided with Dr. Bell's, except that I thought there was some pericardial effusion, though not to any great extent. The treatment was very simple. The points chiefly attended to were, the avoidance of all excitement, simple diet, and a warm dry air, with ample clothing.

Altrincham, Cheshire, September 10, 1853.

FATAL POISONING FROM ARSENIC TAKEN TO INDUCE ABORTION.

By THOMAS BROWN, Esq.

On Monday, October 21st, 1850, I was requested to see Sarah Weston, at the Lock, Weston-on-Trent, a single woman, aged 24 years. On my arrival, I ascertained that she came from her situation as domestic servant at Alvaston, a distance of seven miles, on the Saturday evening previous; and that during the journey she suffered from pain and vomiting, the latter continuing on her arrival at home, where she was prematurely delivered (by a midwife) of a male child. It was not until Monday morning that the friends with whom she lived thought it necessary to send for a surgeon; and, in the meantime, all traces of the matter ejected from the stomach had been removed. I found my patient delirious and unconscious, with a cadaverous countenance, and feeble rapid pulse. The abdomen was tender on pressure, and somewhat distended: there was urgent thirst and constant jactitation. Leeches to the abdomen and an opiate were at once ordered; but no alleviation of the symptoms took place; and death occurred within seven hours from the time I first saw her. In two hours afterwards, the infant of which she had been delivered also died.

Being called in after every actual symptom of poisoning was absent, I attributed the death to peritonitis: and the bodies were speedily interred, without, however, any medical certificate from myself or any other medical practitioner. On the second day of interment, some rumour prevailed that the subject of our case had been the victim of foul play; and this report gaining ground, the coroner for the county at once ordered the body to be exhumed. This was done on the 28th of October, 1850, just three days subsequent to interment.

In company with a neighbouring surgeon (Mr. John Smith), I proceeded to the barn where the body was exposed for examination. On carefully inspecting the oesophagus and cardiac portion of the stomach, there was no appearance of poisoning; but as we traced downwards near the pyloric orifice, we at once perceived erosion or ulceration of the mucous membrane, with a well defined line of demarcation.

I conveyed the stomach to my surgery, and the contents were tested by Marsh's apparatus, as well as by some of the more simple or uncertain modes; but having regard for the stomach (as a specimen of the action of arsenic, which was forwarded to the museum of the Sheffield Infirmary), I forbore subjecting the same to strict analysis, particularly so, as in the evidence adduced at the inquest it was clearly proved that the deceased had procured arsenic, and had taken it for the purpose of procuring abortion. The verdict was in accordance with this evidence.

September 22, 1853.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

DEGENERATION OF MUSCLES: MICROSCOPIC EXAMINATION.

The *Union Médicale* for May 7th, contains an account given by Dr. DUCHENNE, of an examination made by him of the right arm of a man who had died with muscular atrophy.

The subject was a man, aged 32, a mountebank, who had been under the care of M. Cruveilhier, labouring under general atrophy of the muscles, with loss of power of motion. Deglutition, speech, and respiration, gradually became impeded; and he died during an attack of influenza, from inability to dislodge the mucus which accumulated in the bronchial tubes.

A very full account of the case, and of the *post mortem* examination, is contained in an essay read before the Academy of Medicine by M. Cruveilhier, and published in the *Gazette Médicale* for April 16th, 1853.

All the muscles, although much atrophied, had almost preserved their normal colour; these muscles had undergone no change of structure. The brachialis anticus alone presented a pale grey colour. Several of the muscles on the front of the fore-arm were only tendons, having some muscular fibres attached to them; these fibres were for the most part of good colour, and of normal structure. There were no traces whatever of the pronator teres; more deeply, there were found some remains of the muscular fibres belonging to the superficial and deep flexors, and to the pronator quadratus. These fibres varied in colour from yellowish to pale grey. The fibres having the latter colour had the appearance of gelatine more than of muscle. All the muscles of the palmar surface of the hand were in the last stage of depraved nutrition, except some muscular fibres of the hypothenar eminence.

The muscular fibres were examined under the microscope by Dr. Duchenne and MM. Aran and Mandl. Their volume and texture were normal in those muscles which had preserved their colour, and which had been ascertained during life to be obedient to the electric or the voluntary stimulus.

Fig. 1.

Fig. 2

Fig. 3

Fig. 1 represents healthy fibre with transverse striæ. Some longitudinal fibres are seen.

Fig. 2 and 3 represent the first degree of degeneration. The transverse striæ are less distinct; they are frequently interrupted, are lost here and there, and at last are altogether displaced. The longitudinal fibres become more distinct.

Fig. 4.

Fig. 5.

Fig. 4. The transverse striæ have entirely disappeared. Outside the muscular fibre is some adipose tissue; and there are some drops of fat in the fibre.

Fig. 5 represents a portion of fibre, in which the longitudinal fibrils have preserved their character, and are undulated.

Fig. 6.

Fig. 7.

Figs. 6 and 7 represent the third degree of degeneration. The longitudinal fibrils are less distinct; the oily molecules are more abundant, and in Fig. 7 nearly cover the longitudinal fibrils.

Fig. 1.

Fig. 9.

Fig. 10.

These figures represent the fourth degree. The longitudinal fibrils have disappeared; and the oily molecules, having become more abundant and diffused in Fig. 9, are no longer distinct in Fig. 10, in which the fibre appears as an amorphous mass.

Each degree of fatty transformation corresponds to the amount of decoloration of the muscular fibre.

Dr. O'Leary has followed in the tadpoles of frogs the transformation of organic cells into muscular fibres. He has distinguished in this four principal phases, which seem to M. Duchenne to correspond exactly to the four degrees of change through which a muscle passes in assuming fatty degeneration; only the process takes place in the opposite direction. Dr. O'Leary has furnished M. Duchenne with the following account of his observations.

"1. The organic cells which at a later period form the muscular fibre, are at first composed of a transparent envelope, of two or three nuclei, and of a multitude of granular molecules, which present movements in the interior of the cell: these molecules often hide the nuclei. The nuclei are angular and elongated, of different sizes, and reflect light like fat-globules.

This stage continues twenty-four hours after the segmentation of the yolk.

"2. After a certain time, the enveloping membrane disappears; the nuclei become very distinct, being surrounded by granules disseminated over a wider space. These granules soon gradually disappear, and there only remain isolated nuclei, which have acquired a certain degree of growth. This stage continues nearly three days.

"3. Longitudinal lines begin to be formed on the nuclei, as if by a kind of retraction of the matter composing them. These lines become more and more distinct. This stage continues a little more than twenty-five hours; and it is only at the seventh day from the end of segmentation that the longitudinal lines appear. Two days afterwards, the following stage is entered on.

"4. There gradually commences to appear a second series of lines (the transverse striæ), which at last partly conceal the first. At this point, the future muscular tissue is composed of a mass of little parallelograms with transverse striæ and longitudinal lines, the latter being indistinct, and disposed more or less regularly. From this time, the only change which these parallelograms undergo is a simple increase in size in every direction, by means of which they approach each other, and form continuous fibres.

"These observations were all made at intervals of half an hour, during from twelve to fifteen hours at a time. The first stage was watched for forty-eight hours."

HOOPING COUGH AND ASTHMA.

Dr. PERRY, of Matagorda, says, in the *Boston Medical and Surgical Journal*,—"The recent epidemic of whooping-cough was unusually severe, and along the Colorado very fatal. During the acute stage, I did not find nitric acid beneficial; after that had passed, any alternative or nervous sedative seemed to exercise a beneficial effect.

"In young children (under three years), the disease was attended with high fever, bilious vomitings, inflammation of the bowels, and spinach coloured stools, which, if neglected or treated with mercurials, generally proved fatal in four or five days.

"In such cases I found a solution of nitrate of silver, of from four to five grains to the ounce, administered in teaspoonful doses every three or four hours, to act admirably, relieving the cough, and soon changing the nature of the discharges.

"I administered chloroform internally in every stage without benefit. Perhaps I was too cautious. Externally over the throat, and on the spine and abdomen, it sometimes seemed to act well.

"During paroxysms of asthma, I have seen no relief from nitric acid. During the interval, when there has been torpor of the liver, as is apt to follow repeated attacks of the disease, doubtless attributable to the removal of the blood in the organ and destruction of its vessels during the paroxysms, I have thought it very useful, but not otherwise. In the internal use of chloroform, however, we have almost a specific. Administered when the paroxysm is forming, it will generally prevent its full development, and given during its height, will moderate all the urgent and distressing symptoms. I have used it ever since the discovery of the article, and have been generally successful, if not in curing, at least in palliating."

FUSEL OIL IN TUBERCULOSIS.

In the *Virginia Medical and Surgical Journal* for April 1853, we find the following remarks by Dr. MOVILL WYMAN, of Cambridge, U.S.

"The diseases in which I have used fusel oil about a year and a half are tubercular affections of the lungs, and scrofulous diseases generally. The dose is four or five drops three times daily, gradually increased to as large a quantity as the stomach will bear. It is most conveniently given in wine or other alcoholic liquor, with which it readily mixes. I have not thought it did as well with those who have a red tongue, or a tendency to diarrhoea, as with others. The results so far have led me to believe it has a tendency to suspend the action of tubercular disease; but in medicine 'experience is fallacious and judgment difficult', and correct inferences can seldom be drawn except from many cases.

"I was first led to make use of this oil from considering the well known fact, that those in the habitual and excessive use of alcoholic drinks are not subject to tubercular disease in the same proportion as others. By careful inquiry, I was also led to believe that it is the coarse alcoholic drinks which are most

remarkable for this protective quality; New England rum, 'rot-gut' whiskey in this country, and the fusel liquor of the north of Europe; those, in fact, which produce bloating and fattening.

"The most striking difference in the two classes of liquors is in the quantity of fusel oil contained in them, the coarse liquors containing much, the fine liquors very little; indeed, the less they contain, the smoother and less fiery they become. The coarse liquors produce, in fact, a disease which may have a power antagonistic to tubercular degeneration, just as measles and scarlet fever, or measles and typhoid fever, or cancer and phthisis are antagonistic. Thinking, therefore, that the protective power may exist in the fusel oil, I have administered it as a medicine."

OPHTHALMOLOGY.

PRISMATIC SPECTACLES IN STRABISMUS.

The *Medical Times and Gazette* for August 27th contains a paper by Mr. SPENCER WELLS, on the cure of squinting by the use of prismatic spectacles. Theoretically, we shall not enter upon the question; for, indeed, we scarcely understand the principle on which such an apparatus is to act in altering the direction of the squinting eye. Practically, Mr. Wells has tried the plan in three cases; in two, it seemed to be doing some good; in the third, which was a decided case (we presume, from this, that the others were slight), it failed completely, and the author was obliged "to have recourse to the old method of binding up one eye". As we believe that, in most cases, this method is useless, and the new method is thus confessedly its inferior, we shall wait for further evidence of the power of these lenses in curing strabismus.

EPICANTHUS.

We find the record of a bad case of double epicanthus treated successfully by Mr. HAYNES WALTON, by excising a vertical slip of skin on each side of the nose, and bringing the margins together with the hair-lip suture. The disease was cured, and inversion of the nasal extremity of the eyelids removed.

IS MELANOSIS CANCEROUS?

In the January number of the *Annales d'Oculistique*, M. PAMARD writes "à l'infirmer l'opinion généralement admise sur la nature cancéreuse des mélanosis". As we understand it, the matter stands thus. The black substance of melanosis is not cancerous, but it may be combined with, or deposited on or in any structure, normal, benign, or malignant; and the fact is, that, in the majority of cases, it is combined with soft cancer, and hence forms the tumour known as malignant melanosis, which, however, it must be acknowledged, is less malignant, that is, may be removed with less certainty of its being reproduced, than ordinary encephaloid cancer. We think this is, in brief, the state of the question.

EPIPHORA.

In the September number of the *Monthly Journal*, Mr. BENJAMIN BELL records two cases of epiphora from slight displacement of the puncta, as lately described by Mr. BOWMAN, treated successfully, as that gentleman recommends, by slitting up the duct upon a probe, and thus artificially extending the orifice upon the conjunctiva.

OSSIFICATION OF THE VITREOUS BODY.

In Virchow's *Archiv.* for 1853, p. 580, Dr. VON WITTICH has published the dissection of the disorganized and shrunken eye of a man aged 60, in which the posterior part of the vitreous body appeared converted into true bone. The choroid was thrown into shrivelled folds, the capsule of the lens opaque, and the lens itself the subject of earthy deposition. Traces of the retina were found lying behind and surrounding the bony mass which occupied the posterior part of the vitreous humour. This substance was true bone, as evidenced by its numerous corpuscles; it was cup-shaped anteriorly towards the lens, passing into a softer semi-gelatinous substance, which was evidently altered vitreous humour, and upon the anterior surface of which the zonule of Zinn could be distinctly observed. The bony substance sent forward small prominences into this softer matter.

Our author concludes from the true ossification here observed, that the vitreous body possesses a true cell-texture, as, in tissues destitute of this, we may have calcareous matter deposited, but not true bone formed.

PRESBYOPIC AMBLYOPIA.

Under this name, M. SICHEL describes (*Ann. d'Ocul.*, February 1853) the weakness of sight induced in long sighted persons by forcing their eyes to look habitually at objects within their true focal distance; reading, sewing, etc., without the necessary glasses. Now, with all respect to M. Sichel, we cannot help thinking that we have here no novelty, but merely asthenopia, accompanied with more or less ocular congestion and irritation.

Let us keep clearly in view the two elements of this complex malady: *asthenopia*, consisting in an impaired power of adjusting the eye to the vision of near objects; and *amblyopia*, consisting in irritability of the retina, and differing from amaurosis in being a symptom of exhaustion and morbid excitability, and not of paralysis, although it may of course end in that.

The blindness of the amaurotic is constant: that of the amblyopic is induced by exertion of the organ, and disappears when it is allowed to rest; that of the asthenopic is, properly speaking, not blindness at all, since the smallest object can be seen at all events for a few seconds, and distant objects always well. We cannot see why asthenopia, induced in a presbyopic person by injudiciously reading or sewing at the ordinary distance, should in its nature be a different disease from the asthenopia induced in a person of ordinary vision by engraving or watch-making at four or five inches distance. Nor do we think that M. Sichel has much enlightened us in the matter of treatment.

Rest to the eye, and its employment on distant objects only; local depletion, and counterirritation when necessary; and a judicious derivative and alterative general treatment, are surely just the means which any well informed ophthalmic surgeon would use in such cases, keeping always in view that the disease is one of local exhaustion, often complicated with congestion, and almost always with more or less constitutional derangement and debility.

OBSTRUCTION OF THE NASAL DUCT.

In a very prolix paper, M. DUBOIS of Bourdeaux ("ancien élève particulier d'interné de M. le docteur Sichel") recommends the duct to be dilated by catgut bougies soaked in a solution of nitrate of silver, and has painfully investigated the quantities of the salt which they absorb. M. Dubois give one case in which, after a three months' employment of these bougies, he finished the cure by metallic styles! We desiderate more extensive experience.

THE SPARKLING EYE.

This curious appearance, *Synchesis étincelant* of our French friends, obtained some time ago rather more attention than it was worth from certain writers in the *Annales d'Oculistique*. Dr. DIX of Boston, Massachusetts, has published a case of it in the April number of the *Virginia Medical and Surgical Journal*.

"Mr. M. S., aged 32, of Portland, Maine, had for some two years been blind from presumed amaurosis, when, about a year ago, it was observed that in the right eye a distinct and apparently lenticular cataract of a slightly yellowish whiteness existed. The left eye exhibited no affection of the crystalline system, but through the pupil reflected from the fundus of the globe a reddish yellow glare. In the left eye, the iris was tremulous. With the right eye, he had a perception of light; with the left, none.

"Mr. S. being informed that the removal of the cataract could be serviceable only in the event of the eye being found not to be amaurotic like its fellow, chose to avail himself of the very small chance of relief which an operation offered. I confined the first operation to a central division of the capsule, leaving the lens, which seemed to be somewhat more hard than its colour had indicated, *in situ*. Four weeks after, no inflammatory symptoms having occurred, and there being no evidence of absorption in the lens, I divided both the capsule and lens partly; the lens being softer than at the first operation.

"This operation has been repeated some four times in the course of the year. In the two last, the capsule and fragment of lens remaining seemed to be of a leathery toughness, and I reclined it with partial clearing only of the pupil; the cells of the vitreous humour being too much broken up to retain it where it was left by the needle. At the last operation, while in the act of displacing the cataract, I observed an appearance at the fundus like that in the left eye, and do not therefore propose anything further. In the meantime the patient thinks that he sees very much more light, and can at times distinguish large objects, as buildings.

"Two months after the last operation, which was...

some pain for two weeks, without any visible evidence of inflammation, the eye presented the following appearance.

"Throughout the anterior and posterior chambers of the aqueous humour, and as deep in the region of the vitreous humour as it is possible to look, were innumerable brilliant particles, floating and darting about with every motion of the globe, and some of them occasionally decomposing the rays of light and reflecting the prismatic colours. They vary in size from the least visible magnitude to that of a very small pin's head. They are of a little greater specific gravity than the medium in which they float, inasmuch as, when the patient has been for some time erect, a heap of them accumulates in the lower part of the anterior chamber, to the depth of about a third or quarter of a line. After holding the head forward for a few minutes, and then throwing it backwards, they will be seen in great numbers upon the whole surface of the iris, and it was the bright, sanded appearance of the iris which first attracted my attention.

"In reply to a letter from me, Dr. W. E. Chase, the medical adviser of Mr. S. at Portland, writes a year after my last examination of the case: 'The iris seems now almost entirely composed of brilliant particles moving in their places, but remaining attached to the membrane. Throughout the anterior and posterior chambers, an almost inconceivable number of these icy, glassy, brilliant spiculæ are darting in every direction, and really present a very beautiful appearance, to me quite anomalous. I did not observe any in the other eye.'

"From this I infer that a considerable increase of this morbid product (probably cholesterol) has taken place within a year. It should be noted also, that as in the case of Mr. Wilde, it occurred only in an eye subjected to some mechanical disturbance. This case differs from those observed in Europe, by showing a silvery, instead of a golden lustre.

"Mr. S. was of strumous habit and subject to hæmoptysis."

We think there can be no doubt that the sparkling bodies in question are really scaly crystals of cholesterol: they are like them, and like nothing else; and their colour, golden or silvery, will depend on that of the fluid in which they float. We remember opening a small ovarian cyst, the fluid of which swarmed with sparkling yellow crystals, which, separated from the serum by filtration, turned out to be colourless cholesterol.

It is not improbable that disorganisation of the retina may have something to do with the development of this fatty substance in the cavity of the eye.

NEW OPHTHALMOSCOPE.

Mr. T. SPENCER WELLS, in the *Medical Times and Gazette* for September 10, describes and figures an instrument recommended by M. Kotzius of Leipzig, as a great improvement upon the eye speculum of Helmholtz, as a means for illuminating the retina of the living eye, and displaying its aspect in health and in disease. It consists of a perforated mirror and a lens, attached to it by a jointed arm; the mirror is one inch square, and the lens is about an inch in diameter. The rays of light from a bright lamp, placed on the corner of a table in an otherwise dark room, are concentrated by the lens and thrown on the mirror, which, being held before the eye to be examined, throws the rays through the pupil (previously dilated by belladonna) on the retina, from which the light is again reflected through the small central aperture of the mirror to the eye of the observer, placed close behind. The patient and surgeon are of course seated close to one another, and by a little management a good view is obtained of the different parts of the retina.

With the assistance of this instrument, Mr. Wells has himself detected, in various forms of partial or total amaurosis, congestion and varicosity of the vessels of the retina, partial removal of the pigment in patches, and exudations into the substance of the retina, or on its surface. We need not add how much this discovery, should it prove as useful as Mr. Wells believes it to be, will conduce to the better understanding of the various forms of amaurosis, even should it not be found much to aid the treatment of that very imperfectly understood disease.

SCROFULOUS OPHTHALMIA TREATED BY IODINE FUMIGATION.

The *Gazette Médicale de Lyons*, as quoted in the *Gazette des Hôpitaux* for August 6, states that Dr. BOUCHET, physician to the Hôtel Dieu at Lyons, has been very successful in treating scrofulous ophthalmia by means of iodine fumigations.

Several ophthalmologists, and especially Dr. Mackenzie of Glasgow, have described small fungoid granulations as being present on the conjunctiva of the eyelids in cases of scrofulous

ophthalmia. Solid nitrate of silver can only be applied in parts: general cauterisation would be dangerous and painful. Iodine vapour fulfils the object of repressing the granulations without producing much pain.

The iodine may be applied by being vaporised on the heated blade of a knife or any flat instrument, which is held near the eye. But a better method is to place some iodine in a heated metal capsule, to which is fitted a glass tube with an enlargement at the end to fit the eye. The vapour is in this way entirely confined to the eye; and the patient is not suffocated by the fumes.

When the iodine vapour is applied, more or less acute pricking is felt; and sometimes there is a rigor, followed by epiplura.

The conclusions which are drawn are:—

1. Scrofulous ophthalmia may be cured by the use of iodine vapour alone, but only after the treatment has been long persevered in.

2. The cure is more rapid, if the ordinary epithems are at the same time employed.

3. There can be no doubt as to the greater efficiency of the common epithems when employed in conjunction with iodine vapour, than when used alone.

MIDWIFERY AND DISEASES OF WOMEN.

DIAGNOSIS BY AUSCULTATION DURING LABOUR OF A HYDROCEPHALIC FETUS.

At a meeting of the Biological Society of Paris, reported in the *Gazette Médicale* for Sept. 24th, M. BLot stated that twice during his residence as "interne" at the Maternity Hospital of Paris, he had had the opportunity of applying auscultation during labour in a novel way to the diagnosis of hydrocephalus. Twice in hydrocephalic cases in which the disease was so considerable as to present an obstacle to the head entering the superior strait of the pelvis, he found that the maximum intensity of the sounds of the foetal heart corresponded to a point very high up in the abdomen—once, it was on a level with the umbilicus, and the other time it was a little lower down; or, in other words, the maximum intensity was in that situation where it ordinarily exists in pelvic presentations, whilst at the same time the touch established that the head was the presenting part.

M. Blot attaches practical importance to these observations for two reasons, viz.: 1. Because when the nature of the presentation can only be determined by auscultation, a head presentation of a hydrocephalic foetus may exist, and not a breech presentation of a healthy foetus as might be supposed: and 2. Because when we find that with a presenting head we have the maximum intensity of the foetal heart at or near the umbilicus, we may be pretty sure that the foetal head is hydrocephalic, because hydrocephalus is the most common cause of enlargement of the foetal head.

The points insisted on by M. Blot are of some value in a practical point of view; but we have heard the foetal heart loudest at or near the umbilicus in twin cases with a presenting head, when both foetuses were healthy; and in one case of dystocia we remember having heard the same thing, although the pelvis of the mother was not narrow, and the only impediment to labour was the unusual bulk of every part of the foetus, which, two hours after birth, weighed within an ounce of twelve pounds. After a very tedious labour, both mother and child did well. We have before and since attended the same mother in easy and rapid labours. Such cases evidently limit the value of M. Blot's test.

HOLLOW APPARATUS OF VULCANISED INDIA RUBBER AS A MEANS OF ARRESTING HÆMORRHAGE IN PLACENTA PRÆVIA.

The *Annales et Bulletin de la Société de Médecine de Gand*, as quoted in the *Bulletin Général de Thérapeutique* for July 30th, state that M. LADOS employs hollow balls of vulcanised India rubber as a means of arresting uterine hæmorrhage in cases of placenta prævia. When the instrument is introduced in the vagina, he distends it with cold water, by means of a common clyster apparatus. In this way, the water can be easily renewed when its temperature becomes elevated. A similar apparatus has been employed in cases of uterine hæmorrhage by M. Diday, who, however, distended the apparatus with air. Cold applications should at the same time be made to the abdomen and the genital organs, and the pelvis should be elevated. If all these means do not succeed, nothing remains but for the accoucheur to induce labour.

RETROVERSION OF THE UTERUS: MODES OF REDUCTION: RELATION TO RETENTION OF URINE.

A discussion on the subject of Retroversion of the Uterus took place at the meeting of the Académie de Médecine on August 30. We translate it from the *Gazette Médicale* for September 3.

Dr. PRIOU, of Nantes, read an essay, in which he observed that the expressions used by authors in treating of retroversion of the uterus, proved that they only spoke from hearsay. Those, he said, who proposed to introduce the index and middle fingers of the left hand into the vagina, and the same fingers of the right hand into the rectum, could never have required to perform this manoeuvre; for they would have found it impracticable.

The author observed, 1. That when the uterus is firmly wedged in the pelvis, its neck does not offer resistance enough to enable the fingers to be made to bear on it with much power; 2. That the fingers, introduced into the rectum, are not sufficiently long to arrive at the fundus of a retroverted uterus, and which must be pushed beyond the sacro-vertebral projection before it can resume its ordinary position.

In order to replace an uterus retroverted during pregnancy, some authors have advised the introduction of the entire hand into the rectum or vagina. But is this, M. Priou asked, always practicable? It must not, however, be neglected, if it appear at all possible, and especially if other means of reduction have failed.

A lady, when about three months and a half pregnant, had retroversion of the uterus, with constipation and retention of urine. M. Priou at first attempted to depress the neck, which was behind the symphysis pubis, by means of the index and middle fingers of his right hand. Not succeeding in this, he placed the patient on her knees and elbows; he then, by introducing the two fingers into the rectum, succeeded in somewhat raising the fundus. The relief, however, was very incomplete; the retention of urine continued, and the uterus remained in the pelvic cavity. He then proceeded to effect the reduction in the following manner.

The patient having been placed on her knees and elbows, a sound, wrapped in linen and well oiled, was introduced into the rectum, so as to push upwards and forwards; while the operator endeavoured to act downwards and backwards on the cervical portion, by means of the hand introduced into the vagina. Considerable force was required to disengage the uterus from the pelvis. By this method, M. Priou succeeded, not entirely in restoring the uterus to its normal position, but at least in giving it sufficient space for enlargement. At the end of a week, the patient was enabled to leave her bed; and her pregnancy went on favourably to the natural period.

M. MOREAU remembered having met with a similar case about forty years ago, in a lady who was in the third or fourth month of pregnancy. To effect reduction, he introduced a piece of wood into the rectum, and pushed the fundus forward; while with two fingers in the vagina he directed the cervix backwards. Reduction was effected without much difficulty; and the lady was delivered of twins at the full period.

M. CAZEAUX had lately reduced a retroverted uterus in a different manner. The woman was a patient of Dr. Aran, and was pregnant three months. M. Cazeaux at first attempted reduction by introducing the fingers into the vagina; but failing in this, he placed the patient on her knees and elbows, with the pelvis much elevated, and introduced the entire hand into the vagina. He was thus enabled easily to effect reduction, and to push the uterus above the sacro-vertebral angle, where it remained. This mode of reduction appeared to him easy, at least in comparison with the great difficulty which attends other plans.

M. MOREAU had already tried this plan; and it was only after it had several times failed that he had recourse to the stick of wood. The introduction of the hand appeared to him productive of much pain; and he remembered having seen a woman faint while it was being performed, from the pain produced.

M. DEPAUL had met with only one case of retroversion, in which he readily procured replacement by introducing two fingers into the vagina, and two into the rectum. The patient was three and a half months advanced in pregnancy. He believed that each of the three methods described were nearly equally satisfactory in their results.

M. DANYAU observed that, in M. Priou's cases, the retention of urine appeared to be an effect of retroversion. But, in a tolerably large number of cases, the retention of urine must be considered as the cause, and not the effect, of retroversion. In a case of this kind, he had found the bladder enormously distended. He removed a large quantity of urine by the catheter: then, on introducing his fingers into the rectum, he was sur-

prised at the facility with which the uterus was, almost spontaneously, replaced. The opinion that retention of urine is sometimes the cause of retroversion is supported by the authority of Dr. Ramsbotham, who cites a number of cases in proof.

M. CAZEAUX did not perceive, in what M. Danyau had said, any proof that retention of urine was the primary cause of retroversion. Retention of urine is always consecutive to retroversion, which it aggravates and increases: it becomes a secondary cause.

M. MOREAU agreed in the opinion expressed by M. Cazeaux.

FRACTURE OF THE THIGH DURING PREGNANCY: UNION RETARDED UNTIL DELIVERY.

The following case is one of those which show the unfavourable influence exerted by pregnancy on the union of fractured bones. It is reported by M. DUPUY, in the *Journal de Médecine de Bordeaux*; and is quoted in the *Gazette Médicale* for June 25, 1853.

A healthy young woman fractured her left thigh in the third month of her pregnancy. She was admitted into hospital on May 25, 1852. The fracture, which was somewhat oblique, was easily reduced, and the usual apparatus was applied. On the thirtieth day, M. Dupuy found the ends of the bones as moveable as at first. The apparatus was reapplied; and perfect immobility was enjoined. The patient was carefully watched; and the bandages and strings were tightened from time to time, as appeared necessary.

At the end of two months, there was not the slightest appearance of union. The general health continued excellent. A starched bandage was applied, and remained on from July 25 to September 7.

On October 13th, towards the end of the eighth month, the patient was delivered of male twins; they appeared tolerably strong, but lived only a few hours. From this time, consolidation commenced; in a month afterwards, it was perfect, and the callus was solid. There was, however, a slight riding of the ends of the bone on each other.

LEUCORRHOEA OF THE VAGINAL PORTION OF THE UTERUS A CAUSE OF STERILITY.

Leucorrhœa has long been recognised as a cause of sterility; but it has not this effect where it occupies only the urethra and vagina. It is when it occupies the vaginal portion of the uterus, and is accompanied with tumefaction of the neck, that it proves an obstacle to conception. Professor SIGMUND of Vienna relates some cases of this kind in the *Wiener Medicinische Wochenschrift*; they are quoted in the *Gazette Médicale* for Sept. 3.

CASE I. Madame F., aged 23, of good constitution, had been married three and a half years. Four months after marriage, she was attacked with leucorrhœa, which resisted local and general treatment. On examination, there was found to be a moderate discharge from the vagina; the vaginal mucous membrane was pale; the vaginal portion of the cervix was rather red, and very much swollen; the os uteri was obstructed by a viscid plug. Menstruation was normally performed.

Cold water was injected three times a day; the cavity of the cervix and the surrounding parts were superficially touched three times a week with sulphate of copper; generous diet, a little wine, and exercise in the open air, were ordered; and sexual connexion was forbidden. In five months, the leucorrhœa was cured; in the sixth month, the patient became pregnant, and was in due time delivered of a healthy female child, and two years later of a boy.

CASE II. Madame de B., aged 20, of delicate formation, but enjoying good health, had been married six years, and had had leucorrhœa four years. There was vaginal leucorrhœa, increased before and after menstruation; the mucous membrane was slightly red, and the vaginal portion of the uterus was swollen and slightly excoriated, and bled readily; the os uteri was obstructed with a viscid yellowish plug; the cervix was very tender.

The same treatment was adopted. In ten months, the leucorrhœa was cured; three months later, the patient became pregnant, and was in time delivered of a healthy male child.

CASE III. Madame G., aged 27, had been married seven years. The general characters of this case were similar to those of the preceding ones; and the result of the treatment, as regarded the leucorrhœa of the cervix, was the same. The disease, however, reappeared at the end of two months, and was then successfully treated by the application of solid iodine of iron by means of a brush, and a weak solution of zinc. In a year, delivery of a healthy female child.

Dr. Sigmund has met with four similar cases, all which were cured in the same way. He does not pretend that sterility commencing with leucorrhœa of the cervix will always be cured when the latter is removed; but he insists on the necessity of a careful examination of the reproductive organs, and of an appropriate local treatment; because it is evident that leucorrhœa of the cervix, especially when the os is closed by a plug, must be a real obstacle to impregnation. It must be observed that, in all the cases observed by Dr. Sigmund, the leucorrhœa was purely local—a circumstance on which the success of the treatment in a great measure depends.

VARIOLA IN THE FŒTUS.

CASE I. Dr. WM. T. TAYLOR, of Philadelphia, reports the following case of variola in the fœtus in the *American Journal of the Medical Sciences* for July 1853.

"On the 8th of October, 1852, I was requested to visit Mrs. A. H., 26 years of age. On reaching the house, I found that she had miscarried, being in the fifth month of pregnancy. The pains having entirely ceased, I gave half an ounce of the wine of ergot, which soon caused the placenta to be expelled. Upon examining the fœtus, I was greatly astonished to find it completely covered with discrete variola in the pustular stage—apparently about the eighth day of the disease. Some of the pocks were well filled, and rounded on the top, whilst others were depressed in the centre. The mother had been vaccinated when a child; she never had had small-pox, nor had ever seen a case of the disease; but was always fearful of taking the contagion. Referring to a case of confluent variola, which I had attended a few doors from her residence during the early part of September, she remarked:—'I would never pass the house, but always crossed to the other side of the street.' A few weeks previous to her miscarriage, having been seized with a chill, which was followed by headache, sickness of stomach, and a severe pain in the small of the back, she was impressed with the idea that it was small-pox. This occurred on Friday, 24th September. Two days after, an eruption resembling prickly heat appeared on her face and arms. She drank a tea, made of ginger and sweet marjoram, 'to drive out the disease'; and feeling somewhat better did not seek medical advice. On Monday, 27th September, the eruption began to disappear, and on the following day it was entirely gone; but she did not feel perfectly well, for there were occasionally symptoms which she described as flashes of heat, and cold chills running all over her, with a dull aching pain through the stomach, and loss of appetite. These symptoms continued until two days before her abortion, when she felt a weight in the pelvis, attended with bearing down pains, which continued until she parted with the fœtus."

Two cases of intra-uterine variola are reported in the *Gazette Médicale* for September 24th, as having been read before the Société de Biologie.

CASE II. CONFLUENT SMALL-POX IN A FEMALE IN THE SIXTH MONTH OF PREGNANCY: ABORTION AT SIX AND A HALF MONTHS: FŒTUS PRESENTING NUMEROUS SMALL-POX PUSTULES, WITH ULCERATION OF THE STOMACH. By M. CHARCOT. S. D., an Irishwoman, aged 25, was admitted into the hospital of la Charité on April 16th, 1853. She appeared of strong constitution; she had never been vaccinated, nor had measles or scarlatina.

In the middle of the sixth month of pregnancy,—on March 19th,—she had an attack of small-pox, which was attended with much swelling of the face, and during three days by aphonia and dyspnœa. She was ill twenty-seven days.

Ten days after the commencement of the illness, the movements of the fœtus were felt to be more active; they then daily diminished, and towards April 10th they entirely ceased. The process of desquamation had then been going on for several days.

The patient was admitted into hospital to be treated for ophthalmia of the left eye, a sequela of the small-pox. The face was covered with thick crusts: there was no fever. The uterus reached to about three finger-breadths above the umbilicus; the parts of the fœtus could be felt, always in the same position. The patient now felt no fetal movements; she observed that her abdomen was flatter than it had been before her illness. Neither the pulsations of the fetal heart nor the placental murmur could be heard with the stethoscope.

On May 4th, labour pains appeared; and on the next day, at 10 A.M., the woman was delivered of a fœtus, which had probably been dead twenty-four days. The liquor amnii which escaped during labour was of a dark brown colour, and contained meconium, but was not remarkably fœtid.

EXAMINATION OF THE FŒTUS. The fœtus was a male, about thirty-five centimètres (nearly fourteen inches) in length. It was not fetid: but, from the prolonged maceration to which it had been subjected, the epidermis was readily detached.

The two pleuræ were filled with sanguinolent serous fluid. The lungs and thymus gland were quite healthy. The heart was healthy; the ventricles were empty. The liver, spleen, and kidneys were healthy. The peritoneal cavity was filled with a brown serous fluid. The intestines presented nothing remarkable on their external surface; but internally, the mucous membrane of the stomach presented two small round ulcerations of the size of pins' heads; one was seated in the large *cul-de-sac*, the other near the pyloric extremity. The œsophagus, pharynx, larynx, and trachea, presented no trace of ulceration.

On the external surface, pustules of various sizes were observed; they were grouped in a manner circumstantially detailed as follows.

Two large pustules were symmetrically disposed in the midst of the pectoral region on each side. The front of the abdomen was occupied by ten irregularly scattered pustules, of which three were very large. On the back, there were five large scattered pustules; one of which, a quarter of an inch in diameter, appeared formed by the confluence of several smaller ones, and occupied the centre of the lumbar region. On the front of the scrotum, were three small pustules; and five large pustules were scattered over the buttocks. The left upper limb presented twelve large pustules, two only being on the inner surface. On the right arm, there were only four small pustules—three on the summit of the shoulder, and one on the outer and upper part of the forearm. On the right lower limb were five scattered pustules, two of which were at the inner and front part. On the left lower limb were seven pustules, of which three formed a group on the lower third of the posterior and external surface of the leg. There were no pustules on the hands or feet.

The pustules, before the removal of the epidermis, were depressed in the centre; they were well marked, and of a dead white colour. The epidermis, when detached, raised a disk of false membrane; and there was always found in the thickness of the true skin a round ulceration, more or less deep and extensive. The largest ulcerations were four or five millimètres (about one-fifth or one-sixth of an inch) in diameter, and the smallest only two millimètres (three-fourths of an inch). Some of them occupied the whole thickness of the dermis, and at their bottom could be seen the adipose tissue, or even the superficial muscles: in other cases, the adipose tissue was covered by a fine transparent membrane, forming the bottom of the ulcer.

In most cases, the hair follicles in the vicinity of the ulcerations were hypertrophied. In some of the ulcerations, cicatrization had commenced: but some of them were filled with a yellowish cheesy mass, moulded to the shape of the cavity, and always raised with ease. In general, the ulcers in the dermis were conical, and the bottom of the ulcer was smaller than the upper part.

In April 1851, M. Charcot made before the same society some remarks on the structure of the variolous pustules in the fœtus.

CASE II. FŒTUS AGED SIX AND A HALF MONTHS, PRESENTING CICATRICES OF VARIOLOUS PUSTULES. By M. DEPAUL. M. H., aged 26, contracted small-pox about the middle of the sixth month of her second pregnancy. Abortion took place three days after the cessation of the fetal movements.

The fœtus was dead, and appeared to be of about the sixth month. The surface presented a number of yellowish spots, of the form and size of small lentil seeds. The corresponding parts of the skin were hard and thick. The cicatrices were numerous: there were nine on the left side, and four on the right side of the back; five on the front of the chest; one in the left axilla, and two in the right; fifteen on the forehead, and one, very large, on the nose. There were no lesions in the pharynx, larynx, œsophagus, or intestinal canal.

The woman recovered. The surface of her body presented the marks of numerous irregular cicatrices, apparently the results of confluent small-pox.

The above cases suggest, but do not satisfy inquiry. The poison of variola must have circulated in the blood of Mrs. A. H. if her fœtus was born with the eruption of that disease. Did the poison produce in the mother an abortive attempt at variola, as evinced by "the eruption resembling prickly heat", and by the other symptoms described by Dr. Taylor? Again, was the comparative immunity of the mother caused by her having been vaccinated? If the poison of variola can enter the system of a person in whom it cannot produce the characteristic phenomena of the disease, and if it can even circulate between

that person and her foetus, is it not probable that many illnesses which we are called upon to treat are abortive and unrecognisable cases of variola and of other poison diseases?

RUPTURE OF THE UTERUS IN A CAT.

M. LORAIN exhibited to the Société de Biologie de Paris on the 2nd of June, preparations of the uterus, etc., of a cat, which had died under the following circumstances.

The animal had been shut up for three days in a room without food, and had doubtless in consequence made great exertions to escape. Soon after the door was opened, she left the room, and was taken in labour. She produced four young ones, their birth being followed by severe hæmorrhage, which lasted for some hours. For the first three days she was allowed to have one of her kittens; but the secretion of milk was never well established. She suffered acute pain, vomiting, excessive thirst, parched tongue, and tumid abdomen. On the fifth day after delivery she died.

The lesions found on dissection are thus described by M. Lorain:—

The abdomen having been opened by an incision through its anterior wall, the uterus was exposed to view; its left horn appeared retracted and reduced to a very small size, and the right horn much increased in volume and apparently distended by a hard body. Upon several parts of the peritoneal covering of the intestinal tube and the liver, there were small albumino-fibrous masses, of a soft and only slightly adherent character. They were regarded as evidence of peritonitis, although there was no effusion of fluid into the peritoneal cavity. Upon raising the uterus, it was seen that the right horn was adherent to the transverse colon, and also to the mesocolon, by means of a clot of blood protruding from a circular rent in the right horn, of about one *centimètre* (two-fifths of an inch) in diameter. This clot formed a perfect plug, and extended into the uterine cavity. On cutting open the uterus, the left horn was found to be empty; the right horn was distended by a clot, which was solid, resisting, elastic, adherent, and which evidently had been formed for some days. It was the protruding part of this clot which has been already described. For about a *centimètre* around the rent, the uterus was thin and disorganised in its tissue.

TWISTING OF THE UTERUS IN THE COW.

In the Reports of the Société de Biologie, published in the *Gazette Médicale* for September 24, we find an abstract of a paper on twisting of the uterus in the cow, by M. A. GOUBAUX.

Simple or multiple twisting of the uterus has not unfrequently been observed in late years in cows; it takes place at the full period of gestation, and completely obstructs parturition. The author's object was to point out the causes of this accident.

The uterus of the cow, in its general characters, resembles that of the mare; it presents, however, certain peculiarities. Two of these are important, viz.: 1. The direction in which the cornua are turned; 2. The manner in which the organ is suspended by its broad ligaments.

1. The cornua of the uterus are conical, and are connected with the Fallopian tubes: they diverge forwards, downwards, and outwards, so that their upper border is convex, the lower concave. But as each cornua is turned on itself, the concave border is at first inferior, then posterior; and the convex border is at first superior, then anterior.

2. The broad ligaments are very generally not of the same size on the two sides. One, for example, arises from the inner surface of the flank, while that of the other side rises below, or rather in relation with the external angle of the ilium. Sometimes they both arise from the same point on each side. From whatever point they arise, each ligament passes from above downwards, and from without inwards, to terminate on the lower or concave border of each of the cornua of the uterus.

If—which does not always happen—the cornua of the uterus and the broad ligaments are during gestation always developed in the same proportion, the uterus must remain equally balanced: there can be no twisting until one of the balancing forces is destroyed. M. Goubaux observed, with M. Bouley, laceration of the left broad ligament in a cow which died from twisting of the uterus. This is the only case in which he has seen laceration; hence he believes that it is not a common cause of the twisting.

M. Chaveau, in an essay on the *Anatomical Disposition in the Cow of the Uterus and its Appendages, considered in its Surgical Relations*, inserted in the *Recueil de Médecine Vétérinaire* for 1848, writes as follows:

“If we consider that the broad ligaments have, during gestation, acquired a very great development, and that the cornu

opposite to that side on which the foetus is developed is very little increased in size, we can easily understand how the latter should become rolled round the ligament which supports it, thus producing complete twisting of the neck of the uterus. It hence follows that twisting of the uterus must always take place from within outwards, and from below upwards.”

M. Goubaux objects to this explanation as not sufficiently exact. From *post mortem* examinations of cows which have died with twisted uteri, and from experiments on the bodies of cows at the full period of gestation, he has arrived at the conclusion that the affection is due to a greater proportionate development in length of the long than of the broad ligament; so that the former extend much in front of their attached point, and the broad ligaments are thrown altogether backwards. An easy experiment illustrates this. If a body be cut across at the level of the anterior part of the lumbar region, and suspended so that the parts may be in their normal position, it is easy to give the uterus a rotatory movement on itself, so as to produce complete torsion. MM. Goubaux and Bouley once saw a case in which the uterus had made three turns and a half.

SURGERY.

NICKELS' ELASTIC PLASTER.

Mr. NICKELS, of Camberwell Green, has forwarded to us some specimens of a plaster of which he is the patentee. Its novelty consists in the extensibility, in one direction, of the material on which the plaster is spread, so that it is capable of being more accurately fitted to the parts on which it is applied than are the plasters in general use. The material varies in thickness to almost any required amount; and any kind of plaster may be spread on it. We consider Mr. Nickels' plaster an useful addition to our surgical armamentarium.

REPORTS OF SOCIETIES.

BRITISH ASSOCIATION:—SECTIONAL MEETINGS.

EMPLOYMENT OF THE HIGHER SULPHIDES OF CALCIUM AS A MEANS OF PREVENTING AND DESTROYING THE OIDIUM TUCKERI OR GRAPE DISEASE. BY DR. ASTLEY P. PRICE.

The author had employed a solution of pentasulphide of calcium, which having been found to act in no way injuriously to the young shoots of several plants, was applied to the grapes; the object in view being that the compound should be decomposed by carbonic acid, and that the excess of sulphur should be deposited with the carbonate of lime in a uniform and durable covering on the stems and branches of the vines. This was adopted; and although but few applications were made, the stems became coated with a deposit of sulphur, and the disease gradually but effectually diminished, in so much that the houses are now entirely free from any trace of disease or symptoms of infection. The young shoots are in no way injured by its application, and the older wood covered with this deposit of sulphur continues exceedingly healthy.

The following papers were also read:

Chemical Action of the Solar Radiation; by Mr. R. Hunt. Effect of Sulphate of Lime on Vegetable Substances; by Chevalier Claussen. Crystals from the Sea Coast of Africa; by J. Pearsall. SECTION D. ZOOLOGY AND BOTANY, INCLUDING PHYSIOLOGY.

C. C. BABINGTON, Esq., President.

REPRODUCTION OF THE LOWER EXTREMITIES IN WARM BLOODED ANIMALS. BY MR. ALLIS.

The case was that of a common song thrush. In November 1851, it moulted, and had every appearance of dying;

it was reduced to a skeleton and unable to walk; it lay on its back for six weeks, being fed by hand with raw beef, and occasionally with beef-tea and biscuit. Early in 1852 an unusual protuberance appeared at the bottom and in front of the tibia above the ankle joint; from these protuberances perfect tarsi and toes were developed, which came to maturity in about three weeks; this annoyed the bird greatly, and he destroyed the newly-formed members with his beak and by friction on the perch. He moulted again in September 1852; and in November he lost his original tarsi, and new ones were produced. In January last fresh tarsi were again produced; these displaced those formed in November from articulation with the tibia, and the displaced tarsi are now visibly located on the upper edge of those produced in January last, which latter differ greatly from the normal form, being larger and flatter, and bearing a resemblance to the tarsi of aquatic birds. They have feeble though perfectly developed toes, which are sufficient for the purpose of locomotion, and to enable the bird to perch. The living bird, showing the one pair of tarsi overlying those subsequently produced, was exhibited to the section by Mr. R. Cook, of York, its owner.

NATURE OF CILIARY MOTION. BY P. DUNCAN.

The author concluded that the cause of the bending and returning of the cilium resided in the cell-wall which sustained the cilia, and that, to a greater or less extent, the whole of the cell-wall is contractile.

The following papers were also read:

SECTION E. GEOGRAPHY AND ETHNOLOGY.

DR. R. G. LATHAM, President.

ETHNOLOGICAL REMARKS UPON SOME OF THE MORE REMARKABLE VARIETIES OF MANKIND. BY R. G. LATHAM, M.D.

This paper referred to certain races, as represented by individuals now in London: 1. Zulus; 2. Earthmen (so called); 3. Authalians; 4. Asteks (so called).

1. The Zulus. Over and above the characteristics of the great Caffre family, to which these Zulus belong, they have another element of value. The tendency of modern research has been to draw a broad line of distinction between the Caffre and the ordinary Negro. Undoubtedly, points of difference exist between the more marked and typical forms of the two families. The present individuals, however, break down the supposed difference, rather than confirm it—and (assuming that the extent to which the typical Caffre of the Cape is contrasted with the ordinary Negro has not been exaggerated) they are valuable as specimens of transition.

2. Earthmen (so called). The term Earthmen is correct, so far as the two individuals to whom it is applied are members of the Bushman family, occupying a country whereof the geolo-

gical structure affords them caves and similar forms of shelter as the equivalents of houses. They are Bushmen Troglodytes, or (if the expression be preferable) Troglodyte Bushmen. Except so far as the imperfect character of their domestic architecture is the measure of their inferiority, they are in the same category with the other members of the family to which they belong—viz., the Bushman (or Saab) branch of the Hottentot. They seem to represent an extreme type, and to be of unmixed blood.

3. Aethalians. These have not been publicly exhibited. Their locality is the parts about Cape York; their language the Cowreaga. The height of the taller of the two was 5 feet 10 in., of the shorter 5 feet 9 in.; the chest was well developed, but the lower extremities were so attenuated as to show that the representation of the two Aethalians in Dr. Prichard's one-volume edition is by no means exaggerated. The skin was black; the forehead prominent (the capacity of the skull being small); the sclerotic yellow; the nose broad at base, aquiline, and very characteristic. They held little conversation with each other; so little that, at first, they were supposed to either belong to hostile tribes, or to speak mutually unintelligible languages. This, however, was found, on examination, not to be the case. The temperament was gloomy in one, lively in the other; neither, however, seemed to be unsusceptible to the influences of kind treatment; on the contrary, they showed visible signs of emotion on parting with the people of the house wherein they had passed a fortnight. They showed great power of that kind of imitation which consists in telling a story in dumb show. Their hair was more crisp and curled than straight; and this is, perhaps, the most important feature of their physiognomy. The idea of Papuan intermixture was entertained, but no proofs of it could be found. They are probably full-blooded Aethalians.

4. Asteks (so called). Considering that representations of heads similar to those of the two so-called Asteks are found on certain Mexican monuments; that in the case of the Lacondon and Indians, on the frontiers of Vera Paly and Yucatan, there is an actual instance of a still-existing imperfect independence; that there is special evidence to the existence of goitre in the localities around, it is considered that the individuals in question represent American analogies of the European cretin, where the same conditions that have made arrest of development endemic, have preserved an imperfect independence.

SECTION F. STATISTICS.

J. HEYWOOD, Esq., M.P., President.

ANALYSIS OF THE MORTALITY FROM CHOLERA IN HULL IN THE AUTUMN OF 1849. BY DR. H. COOPER.

By tables was shown the total number of cholera and diarrhoea cases: the former, viz., 1,860, or one in 43 of the whole population; the latter 256, or one in 355. The number of cases occurring in males was 885; in females 975. Yet, allowing for the difference of number between the excess in the whole population, the female mortality was the greatest—one male having died to 1.1 female; while, in the whole population, there is one male living to 1.14 female. The diarrhoea return showed no difference in the number of the sexes. The cases were next analysed as regards age; and it was shown that in cholera the infant mortality, though very high, was not higher than that which occurs from ordinary causes of death at the

same age. The greatest mortality, compared with the annual average, appears to have occurred in the prime of life (from 30 to 35), where the ordinary mortality is very low. There is also an excessive mortality about 60; while the greatest immunity seems to be enjoyed from 15 to 25, and from 40 to 60. In diarrhoea, the important feature is, the great excess of infant and old age mortality. The localities in which there had been the greatest mortality were indicated by marking each death upon a map in the place in which it occurred. The map was tinted in shades; showing by deeper shades the parts of the borough where the levels were the lowest, and in which, therefore, the hygienic condition, as regards moisture and drainage, might be presumed to be the most defective. Three principles were found to govern and determine the position of the greatest mortality: the level, the density of the population, and their physical and social character. These points were illustrated by specifying certain localities in which the number of markings showed the disease to have been rife. The last analysis shown was that of occupation, which showed several curious results. The general inference from this analysis was, that 1,738 of the labouring classes and 122 of the gentry, traders, and well-to-do classes had suffered; and, assuming the former class to amount to 67,000, and the latter to 13,000, it follows that 1 in 40 of the labouring class, and 1 in 131 of the well-to-do class, were victims.

The following papers were also read:

Statistics of the Produce of the Northern Whale Fisheries from 1772 to 1852; by H. Munroe. On Decimal Coinage; by T. W. Rathbone. The Results of the Census of Great Britain in 1851, with a Description of the Machinery and Processes employed to obtain the Returns; by E. Cheshire. Electoral Statistics of the United Kingdom; by J. Edwards. Prevalence of Disease in Hull; by Dr. Cooper. Causes, Extent, and Preventives of Crime, with special reference to Hull; by the Rev. J. Selkirk. Result of some Researches relative to the new supplies of Gold, and to the Circulation of Bills of Exchange, 1848-52; by W. Newmarch. Summary of the Census of Switzerland; by Professor P. Chaix. Excessive Emigration and its Reparative Agencies in Ireland; by Mr. Locke. Suggestions for an Improved System of Currency and Banking; by Mr. Bennoch. Education of the Poor in Liverpool; by Dr. Hume.

SECTION G. MECHANICAL SCIENCE.

W. FAIRBAIRN, Esq., President.

NEW THERMOSTAT FOR REGULATING TEMPERATURE AND VENTILATION. BY W. SYKES WARD.

This apparatus consists of a series of flat circular hollow cases, about one foot in diameter and one inch deep, attached together in their centres. Each case contains a small quantity of sulphuric ether, which is readily affected by change of temperature. The cases, comprising about six, are suspended one under the other, and to the lowest one is attached a weight by a cord that passes over an eccentric pulley. On an increase of temperature the ether expands, and the weight falls down, and it is drawn up again by the pressure of the atmosphere on the external discs or the cases when the air is cooled. By connecting the weight with the ventilators of a conservatory, or other building, the temperature can be thus regulated to any required degree by a previous adjustment of the apparatus.

The following papers were also read:

Introductory Address on General Improvements in Mechanical Science during the past year; by W. Fairbairn. Report of the Committee appointed in 1852 to prepare a Memorial to the Hon. East India Company on the Means of Cooling Air in Tropical Climates; by W. J. M. Rankine. On Reaping Machinery; by A. Crosskill. The Rise, Progress, and Present Condition of Steam Navigation in Hull; by J. Oldham. A brief Description of Locking and Cook's Rotatory Valve Engines; by G. Locking. On Railway Accidents by Collision, and their Prevention; by the Rev. Dr. Scoresby; also by the Rev. F. F. Statham. A Description of some of the large Valves and other Machinery which have been employed for the Discharge of Water at the Manchester Waterworks; by J. F. Bateman. The Tubular, or Double Life-Boat; by Colonel Chesney. Recent Improvements in Machines for Tilling Land; by B. Samuelson. Experimental Researches to determine the Strength of Locomotive Boilers, and the Causes which lead to their Explosion; by W. Fairbairn. Experimental Apparatus to determine the Efficiency of the Jet Pump; by J. Thomson. Improvements in Machinery for Grinding Corn; by W. Crosskill.

[Abstracts of many of the papers read are given in the *Transactions*. We have been obliged to content ourselves with the

part with merely giving the titles; but, besides those few of which we insert abstracts, there are many which would interest those of our professional brethren who have inclination and opportunity to attend to the investigation of scientific subjects.]

ASSOCIATION INTELLIGENCE.

SUFFOLK BRANCH:—FIRST SOIRÉE MÉDICALE.

The first of a proposed series of Medical Soirées was held at the White Horse, Ipswich, on the 2nd of September.

The following gentlemen were present: A. H. Bartlett, Esq. (Ipswich); G. Bullen, Jun., Esq. (Ipswich); B. Chevallier, M.D. (Ipswich); C. M. Durrant, M.D. (Ipswich); J. C. Edwards, Esq. (Ipswich); T. H. Fenn, Esq. (Nayland); C. C. Hammond, Esq. (Ipswich); John Kirkman, M.D. (Melton); Robert Martin, Esq. (Holbrook), President; C. Mingay, Esq. (Dedham); George Sampson, Esq. (Ipswich).

PRESIDENT'S ADDRESS.

The PRESIDENT, having welcomed the members to the first of what he trusted would prove a series of useful meetings, and explained the origin of the "Soirées Médicales", stated that their object was not exclusively confined to the consideration of strictly medical topics, but that they should afford opportunity for the discussion of many subjects, which the limited time allotted to the annual meetings could not entertain; and that they should supply the means by which, on all matters of medico-political importance, the views and wishes of the Suffolk Branch of the Medical and Surgical Association may be made known to the parent society. He observed that such an organism established throughout the kingdom would indeed render the Association powerful for good; it would be correctly impressed with the feelings and requirements of the profession at large, while its own concentrated force would be immensely increased by the exertion of the influence of its various branches with the representatives in Parliament of their respective localities. In effecting any public measure, the President observed, delays and difficulties must be anticipated; but he was sanguine in the expectation, that the example the Suffolk Branch had set would receive general adoption, and that a machinery would thus be set in motion, capable of righting our profession, and obtaining for it the *locus standi* in society which it so lamentably needs, and to which it is so justly entitled.

TITLE OF THE MEETING.

Dr. DURRANT proposed, and T. H. FENN, Esq., seconded, "That this meeting bear the name of the Ipswich Quarterly Soirée Médicale, in connexion with the Suffolk Branch of the Provincial Association."

Dr. CHEVALLIER proposed, and C. HAMMOND, Esq., seconded, "That any duly qualified members of the medical profession may be invited and introduced to these meetings by a member of the Provincial Association."

PAPERS AND COMMUNICATIONS READ.

After some general conversation on the Medical Reform and Vaccination Bills—

Dr. DURRANT read an interesting paper "On the Predominance of Nervous Affections within the last few months". He also stated some favourable results from cod-liver oil in several cases of ocular, lingual, and facial neuralgia.

Mr. SAMPSON introduced a case of fungus hematodes of the orbit, the eye not being affected.

Mr. FENN related some cases of hydrocele, cured by simple puncture with a needle. These cases led to considerable discussion.

Dr. KIRKMAN read a paper on Paralytic Mania, its pathology and physiology, illustrated by several instructive cases.

The members were favoured by Mr. HAMMOND by some valuable illustrations with his microscope: and the first meeting of this proposed series ended with pleasure and profit.

DECISION OF THE CENTRAL COUNCIL REGARDING THE TRANSACTIONS.

Resolved—That it appears to this Council that the Reports read at Swansea are the property of the whole Association, and can therefore only be published by the Association for the benefit of the whole body; this Council therefore cannot sanc-

tion their publication by any limited number of members with an additional subscription, nor can they at present take the responsibility of their publication on themselves, because they have no available funds for that purpose.

Resolved—That the Secretary be requested to confer with the authors of the various reports and papers, and with the editor of the Journal, on the propriety of publishing them in the Journal, or of postponing their publication until the finances of the Association will permit the outlay.

JAMES P. SHEPPARD, *Secretary*.

[These resolutions were unanimously passed by the Central Council on the 17th, and were communicated to us by the Secretary on the 24th September, but we have not received any additional information. We are inclined to think that unless the Reports are heavily laden with tabular matter, their publication in the Journal might be accomplished at an expense quite within our means; but till we have seen the MSS., it is impossible to form any estimate of the cost of producing them. As the decision of the Central Council is conclusive against the publication of Transactions for a section of members by a separate subscription, we trust that those gentlemen who have addressed us for and against such a scheme, will see the propriety of our not inserting their letters.—EDITOR.]

MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on September 27th, the Treasurer announced that in July last the sum due to him was £20; since the above date, the sum of £100:17 had been received in subscriptions, and £28:4 in donations; the payments for benevolent aid, etc., being £80:10, leaving a balance due to the Treasurer of £15:4.

The following cases were considered and relieved:—

i. An elderly medical man who had practised thirty years in the parish of St. Mary-le-bone; after many losses and misfortunes, he is now in great distress. Recommended by Mr. Squibb and Mr. Lavies. Voted £5.

ii. The widow of a medical man residing in the east of London; she has to support a son, who is a medical man, but insane. Recommended by Mr. Self, Mr. Falconer, and Mr. Wilson. Voted £10.

iii. The widow of a surgeon who died after a long illness, leaving six children, under eleven years of age, wholly unprovided for. Recommended by Mr. Lord, Mr. Alford, and Mr. R. T. Smith. Voted £20; £10 to be given now, and £10 in six months.

iv. The widow of a surgeon who died from cholera in 1849. Relieved previously. Voted £5.

Several other cases were brought before the Committee; some were passed over as incomplete, or as not being suitable; others were deferred for further investigation.

EDITOR'S LETTER BOX.

THE NEW VACCINATION ACT AND PRIVATE PRACTICE.

LETTER TO THE EDITOR.

SIR,—That monster of injustice to the profession—the Vaccination Extension Bill—is now the law of the land: and surely, if it accomplishes nothing further than arousing a determination on the part of the medical practitioners to resist by a combined effort any further encroachments of a like character on their duties and their privileges, it will accomplish much. Based as it is on false principles, it never will effect what its promoters anticipate. That it will tend more than ever to engender a bad feeling and repugnance towards the practice of vaccination, even more than the act of 1840, is not difficult to see. A stand, immediate and determinate, ought to be made by the profession at large.

The injustice of the Act towards the private practitioner is very great; because it compels him to vaccinate numbers gratuitously, to prevent the parish doctor from interfering with his patients; and it appears that this is calculated upon by the guardians. The Act empowers them to contract with any medical practitioner. They contract, however, only with their own medical officers: and this, they say, will compel private practitioners to vaccinate their own patients, all which will be a saving to them! And of course they calculate upon private

practitioners giving certificates, etc., "without fee or reward" such "fee or reward" for similar duties performed by the union surgeon, be it remarked, is worthy of 1s. 6d. or 2s. 6d., as the case may be.

Another reason for this conduct on the part of the guardians is, that it appeases somewhat the complainers among their medical staff, by increasing their emoluments. They think that it cannot be wrong to take a slice off the general practitioner's loaf, and give it to the parish doctor. It also increases the fees of registrars—a body very badly paid for very onerous duties, no doubt.

Now, let us for a moment examine the working of the Act. It is contemplated that all the vaccinating, or the bulk of it, will be done by parish surgeons. These in many instances spread the report that they only are authorised by Government to vaccinate, and urge all to come to them—and this even when a child has been vaccinated by the family attendant. Thus it too frequently engenders a bad feeling between union surgeons and the private practitioner: and this appears to be one end which the guardians and the Poor-law Commissioners have in view, judging from their treatment of the latter. And yet, when cholera comes, they expect his aid to be sought; and I suppose, as usual, "without fee or reward".

The way in which vaccination was carried out by the officers of the old Act, as regards efficiency, etc., no doubt causes them to select the same operators again: yet I find, on referring to the *Medical Gazette* of a few years back, a case published of a public vaccinator (an union surgeon, of course) contracting with the guardians for 1s. 6d. a case, and employing a deputy, not a professional man, but a framework knitter (I believe), and giving him 3d. out of each case for his trouble: and I dare say the same public functionary is at the present time recommended and sanctioned as a fit person for the duties of vaccination.

Again: those medical men who are registrars as well as union surgeons will be glad of the present Act. To them the increase of salary will be an object; as they will find a ready excuse, and a neat opportunity, whilst registering the child, to hint that *they only* are duly authorised by Government to vaccinate: and the insinuation will be easily completed by the parents—that *none other* are authorised.

Finally: the poorer part of the population, be it said to England's disgrace, are the most unhealthy—living of necessity in habitations, often supplied by their richer neighbours, where fresh air and pure water find no access; and, moreover, compelled to gather around their very doors hotbeds of filth, manure heaps, cesspools, etc., engendering disease in every quarter. Yet it is from children bred, and born, and reared, or attempted to be reared, in such hovels as these, that we are to take vaccine matter, and then insert it in the arms of the children of the middle or upper classes. Could this be carried out effectually, and were the children of the often wealthy owners of cottage property to be vaccinated from the arms of the poor inhabitants of such cottages, richly would they be rewarded for the care they take of the poor, by witnessing in their own children the outbreak of unsightly diseases, such as are too often prevalent amongst the former.

There was one line of evenhanded justice which might have been followed. It was this: to furnish every duly qualified medical practitioner with a Case Book; to require him to make quarterly returns to the guardians of each district; and that the guardians should pay each and every practitioner furnishing such returns. In this way, every child would have been vaccinated; families would not have been intruded upon by a parish doctor; and every practitioner in the land would have been interested in furthering the extension of vaccination. This plan can be adopted under the Act. But the Poor-law Commissioners step in, and compel the guardians to contract *only* with their own medical officers. This was one main reason why the Act of 1840 proved abortive; and it again threatens to render that of 1853 a useless though more expensive piece of parliamentary lumber.

The Act comes into operation on October 1. Could not something be done before that time to prevent the Poor-law Commissioners from thus acting? or cannot the guardians be made to deal justly with the provisions of the Act? The Act does *not* expressly state that the guardians shall *only* contract with parish surgeons. Are they, or ought they, to be allowed to do this injustice with impunity?

I am, etc.,

A PRIVATE PRACTITIONER.

September 20th, 1853.

COMPULSORY VACCINATION IN PRIVATE PRACTICE.

LETTER TO THE EDITOR.

SIR,—I have this day received four books from the clerk of the Board of Guardians, with a note requesting me to attend to the various insertions, etc., respecting compulsory vaccination.

I take the liberty to trespass upon your time, for *your* opinion respecting the same, as I am at a loss altogether about the matter. Am I, as a private practitioner, compelled to return an account of all my *private* patients?

There is an appointed vaccinator in my village, and he has a large district, and no fixed places except his residence where to attend; neither are any days appointed: this I consider a loose way of carrying out the act.

Can I vaccinate, and charge the Poor Law Board with all I do? I am a medical officer for a district, but not an appointed vaccinator.

Your obliging me with a reply in the next number of the Journal, under the head of correspondents, I shall esteem a great favour.

I am, etc., H. P.

[Insist upon your right morally if not legally to be appointed a vaccinator.—EDITOR.]

AN APOLOGY FOR THE CLUB SYSTEM.

LETTER TO THE EDITOR.

SIR,—I have read several letters in our Journal condemning the club system. I know not in what position the gentlemen who write these letters may be; but I think, that had they understood a little more of the difficulties that beset a young man's entry into practice, they might have thought more, and written less.

I hold the appointment of surgeon to several benefit societies; and as they admit only males of adult age, I find but little illness among the members, and they therefore pay me very well.

Has it never occurred to the writers of these letters, or to yourself, to feel the advantages of a stated time when you may lay your hand on a certain sum of money?

In the intercourse I have with several medical men, I have heard it urged as an excuse for their not having insured their lives, and so making a provision for their families at their decease, that they never were sure of having the money when the premiums became due.

Now, had some of the gentlemen either possessed appointments to a club, or to the much abused union district, this would not have been the case; and we should then hear less of benevolent Mr. Newnham's plaintive appeals, and there would be a much inferior necessity for the Medical Benevolent College.

Before condemning the practice of others, it is perhaps as well to look at home, and inquire a little more into the subject, before it is held up to so much vituperation, and so much written against the system.

When old surgeons learn to treat their juniors with a little more consideration, and to snub them less, and do not talk so much of their being *only very young men*, then will be the time for "medical ethics", and a much more liberal feeling of one man towards another will exist in the ranks of the profession.

I am, etc.,

A YOUNG MEMBER OF THE ASSOCIATION.

Kent, September 27th, 1853.

[We are not opposed to the club system. We only wish to see it reformed. The remarks of a Young Member merit attention from at least some senior practitioners.—EDITOR.]

DR. MAYNE'S EXPOSITORY LEXICON.

LETTER TO THE EDITOR.

SIR,—Allow me, through the medium of the *ASSOCIATION JOURNAL*, to direct Dr. Mayne's attention to a glaring defect in the commercial arrangements of his Expository Lexicon. It is this: that the price of the work to subscribers is not less than to ordinary purchasers. Hence the latter have an advantage over the subscribers; for while each subscriber pays thirty shillings, a non-subscriber may obtain the Lexicon at a bookseller's at a reduction of ten, or perhaps more, per cent., according to the present usages of the trade.

I would suggest to Dr. Mayne to reduce the price of subscribers' copies from thirty shillings to twenty-four or twenty-five shillings.

Trusting that the author may be encouraged to make this valuable work to a conclusion,

I am, etc.,

October 4th, 1853.

NEWS AND TOPICS OF THE DAY.

AN ACT FURTHER TO EXTEND AND MAKE COMPULSORY THE PRACTICE OF VACCINATION.

[16 and 17 Victoria, cap. 100].

Whereas an Act was passed in the fourth year of the reign of her present Majesty, intituled *An Act to extend the Practice of Vaccination*: And whereas an Act was passed in the fifth year of the same reign, intituled *An Act to amend an Act to extend the Practice of Vaccination*: And whereas it is expedient that the practice of Vaccination should be still further extended. Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

I. Within six weeks after the passing of this Act the guardians of every parish or union, and the overseers of every parish in which relief to the poor shall not be administered by guardians, in *England and Wales*, shall, subject to the approval of the Poor-Law Board, divide such parish or union, if need be, into convenient districts for the purpose of affording increased facilities for the vaccination of the poor, and shall appoint a convenient place in each such district for the performance of such vaccination, and shall take the most effectual means for giving from time to time to all persons resident within such district due notice of the days and hours at which the medical officer or practitioner contracted with for such purpose will attend at such place to vaccinate all persons not already successfully vaccinated who may then appear there, and also of the days and hours at which such medical officer or practitioner will attend at such place to inspect the progress of such vaccination in the persons so vaccinated.

II. The father or mother of every child born in *England or Wales* after the first day of August in the year of our Lord one thousand eight hundred and fifty-three, shall, within three calendar months after the birth of the said child, or in the event of the death, illness, absence, or inability of the father and mother, then the person who shall have the care, nurture, or custody of the said child, shall within four calendar months after the birth of such child take or cause to be taken the said child to the medical officer or practitioner appointed in the union or parish in which the said child is resident according to the provisions of the first recited Act, for the purpose of being vaccinated, unless he shall have been previously vaccinated by some duly qualified medical practitioner, and the vaccination duly certified, and the said medical officer or practitioner so appointed shall and he is hereby required thereupon, or as soon after as it may conveniently and properly be done, to vaccinate the said child.

III. Upon the eighth day following the day on which any child has been vaccinated as aforesaid, the father or mother, or other person having the care, nurture, or custody of the said child, shall again take or cause to be taken the said child to the medical officer or practitioner by whom the operation was performed, in order that such medical officer or practitioner may ascertain by inspection the result of such operation.

IV. Upon and immediately after the successful vaccination of any child the medical officer or practitioner who shall have performed the operation shall deliver to the father or mother of the said child, or to the person who shall have the care, nurture, or custody of the said child, a certificate under his hand, according to the form of schedule hereinafter inserted, marked (A.), that the said child has been successfully vaccinated, and shall also transmit a duplicate of the said certificate to the Registrar of births and deaths of the subdistrict in which the operation was performed; and such certificate shall, without further proof, be admissible as evidence of the successful vaccination of such child in any information or complaint which shall be brought against the father or mother of the said child, or against the person who shall have had the care, nurture, or custody of such child as aforesaid, for noncompliance with the provisions of this Act.

V. If any medical officer or practitioner shall be of opinion that any child is not in a fit and proper state to be successfully vaccinated, he shall thereupon and immediately deliver, without fee or reward, to the father or mother of such child, or the person having the care, nurture, or custody of the said child, a certificate under his hand according to the form of schedule hereinafter inserted, marked (B.), that the child is in an unfit state for successful vaccination, and such certificate shall remain in force for two calendar months from its delivery as aforesaid; and the

father or mother of the said child, or the person having the care, nurture, or custody of the said child, shall, unless they shall within each succeeding period of two months have obtained from a medical officer or practitioner a renewal of such certificate, within two months next after the delivery of the said certificate as aforesaid, and if the said child be not vaccinated at or by the termination of such period of two months then during each succeeding period of two calendar months until such child has been successfully vaccinated, take or cause to be taken to the said medical officer or practitioner such child to be vaccinated by him; and if the said medical officer or practitioner deem the said child to be then in a fit and proper state for successful vaccination, he shall forthwith vaccinate it accordingly, and shall deliver to the father or mother of such child, or person having the care, nurture, or custody of such child, a certificate under his hand according to the form of schedule hereinafter inserted, marked (A.), that such child has been successfully vaccinated; but if the said medical officer or practitioner be of opinion that the child is still in an unfit state for successful vaccination, then he shall again deliver to the father or mother of such child, or person having the care, nurture, or custody of the said child, a certificate under his hand, according to the said form of schedule (B.), that the child is still in an unfit state for successful vaccination: and the said medical officer or practitioner, so long as such child remains in an unfit state for vaccination, and unvaccinated, shall at the expiration of every succeeding period of two calendar months, deliver, if required, to the said father or mother of such child, or person having the care, nurture, or custody of such child, a fresh certificate under his hand according to the said form of schedule; and the production of such certificate shall be a sufficient defence against any complaint which shall be brought against the said father or mother, or person having the care, nurture, or custody of such child for noncompliance with the provisions of this Act.

VI. In all contracts to be hereafter made under the provisions of the first-recited act by any guardians or overseers of the poor with any medical officers or practitioners for the vaccination of the persons resident in their respective unions or parishes the sums contracted to be paid shall not be less than the following rates; that is to say, for every person successfully vaccinated at the residence of such medical officer or practitioner, or within two miles therefrom by the nearest public road, a sum not less than one shilling and sixpence, and for every person successfully vaccinated at any place more than two miles distant from such residence any sum not less than two shillings and sixpence.

VII. In the event of any medical practitioner acting under the provisions of this act being of opinion that any child that has been vaccinated by him is insusceptible of the vaccine disease, he shall deliver to the father or mother, or person having the care, nurture, or custody of such child, a certificate under his hand according to the form of schedule hereinafter inserted, marked (D); and the production of such certificate shall be a sufficient defence against any complaint which may be brought against the said father, mother, or person having the care, nurture, or custody of such child for noncompliance with the provisions of this act.

VIII. The registrar of births and deaths in every sub-district in which the operation has been performed shall keep a register of the persons of whose successful vaccination a certificate shall have been transmitted to him as above provided by the said medical officer or practitioner, and shall at all reasonable times allow searches to be made of any such register book in his keeping, and shall give a copy, certified under his hand, of any entry or entries in the same, on payment of the fee of one shilling for each search, and sixpence for each certificate.

IX. The registrar of births and deaths in every sub-district shall, on or within seven days after the registration of the birth of any child not already vaccinated within the said sub-district, give notice in writing in manner hereinafter directed, and according to the form of schedule hereinafter inserted, marked (C), to the father or mother of such child, or in the event of the death, illness, absence, or inability from sickness or otherwise of the father and mother, then to the person upon whom the care, nurture, or custody of such child shall have devolved, that it is the duty of such father or mother, or person having the care, nurture, or custody of such child as aforesaid, to take care that the said child shall be vaccinated in the manner directed by this act, and shall together therewith deliver to such person a notice of the days, hours, and places within the district of such registrar at which the medical officer or practitioner as hereinbefore provided will attend for the purpose of vaccination; and if after such notice the father or mother of the said child, or the person so having as aforesaid the care, nurture, or custody

of the said child, shall not cause such child to be vaccinated, or shall not on the eighth day after the vaccination has been performed take or cause to be taken such child for inspection according to the provisions in this act respectively contained, then such father or mother, or person having the care, nurture, or custody of such child as aforesaid, so offending, shall forfeit a sum not exceeding twenty shillings.

x. A fee of threepence shall be paid to such registrar for each child vaccinated in respect of which he shall have performed the duties required in this act; and he shall keep a book, to be provided as hereinafter directed, containing a minute of his having duly given such notice as hereinbefore directed; and the said fee shall be payable in the same manner as the fee now payable to such registrar for registering the birth of such child as aforesaid is paid.

xi. The Registrar-General for England and Wales shall and he is empowered and directed, within two months after the passing of this act, to frame and provide such books, forms, and regulations, as he may deem requisite for carrying into full effect the provisions of this act; and shall transmit the same to the superintendent registrars of each district in England and Wales, who shall deliver to the medical officers so appointed as aforesaid, and other duly qualified medical practitioners in the said district, such of the said books, forms, and regulations, as they may require for the performance of the duties imposed upon them by this act; and the expenses to be incurred by the Registrar-General under the provisions of this act shall be defrayed in the same manner as the expenses under the act of the sixth and seventh years of King William the Fourth, chapter eighty-five.

xii. All penalties by this act imposed shall be recoverable before any two justices of the peace for the county, city, borough, or place where the offence may have been committed; and the provisions of the act of the twelfth year of Her present Majesty, chapter forty-three, shall be applicable to the recovery of such penalties.

xiii. All penalties recovered under this act shall be applied in aid of the funds applicable to the relief of the poor in the parish or place maintaining its own poor wherein the offence may have been committed.

Schedules referred to by this Act.

SCHEDULE (A).

I, the undersigned, hereby certify, that _____, the child of _____, aged _____, of the parish of _____, in the county of _____, has been successfully vaccinated by me.
Dated this _____ day of _____, 185 _____.

(Signed) A.B.,

Surgeon of the Union or Parish (or other Medical Practitioner, as the case may be).

SCHEDULE (B).

I, the undersigned, hereby certify that I am of opinion that _____, the child of _____, of the parish of _____, in the county of _____, aged _____, is not now in a fit and proper state to be successfully vaccinated, and I do hereby postpone the vaccination until the _____ day of _____.
Dated this _____ day of _____, 185 _____.

(Signed) A.B.,

Surgeon of the Union or Parish (or other Medical Practitioner, as the case may be).

SCHEDULE (C).

I, the undersigned, hereby give you notice, and require you to have C.D. vaccinated within three (or four, as the case may be, according to the Second Section of this Act) months after the birth, pursuant to the Provisions and Directions of the Act of the 16 Victoria, cap. _____. As witness my hand this day of _____, 185 _____.

J.B.,

Registrar of Births and Deaths for the _____ sub-district (as the case may be).

SCHEDULE (D).

I, the undersigned, hereby certify that I am of opinion that _____, the child of _____, of the parish of _____, in the county of _____, is insusceptible of the vaccine disease.
Dated this _____ day of _____, 185 _____.

(Signed) A.B.,

Surgeon of the Union or Parish of _____ (or other Medical Practitioner, as the case may be).

COMPULSORY VACCINATION ACT. The act passed in the last session of Parliament, which makes it compulsory on the father or mother of every child born in England and Wales after August 1, 1853, to have the said child vaccinated within three calendar months, is now in operation. The duty of drawing up and issuing the various certificates and instructions for carrying out the provisions of this Act has devolved upon the Registrar-General, and the completeness and celerity with which this has been accomplished would astonish those who believe that nothing can be quickly and thoroughly executed in Government offices. It may be interesting to remark, that the issue of documents by the Registrar-General under this Act involved the supply of the following items:—3,000,000 forms of "certificate of successful vaccination" (schedule A.), made up into 30,000 books of 100 forms each, with an example prefixed; 3,000,000 forms of "duplicate certificate of successful vaccination" (schedule A.), made up into 30,000 books of 100 forms each; 750,000 forms of "certificate of unfitness for successful vaccination" (schedule B.), made up into 15,000 books of 50 forms each, with an example prefixed; 750,000 forms of "certificate of incapacity to receive the vaccine disease" (schedule D.), made up into 15,000 books of 50 forms each with example prefixed; 1,500,000 forms of "notice" (according to schedule C.), addressed to the "father or mother of the child, printed on loose sheets of foolscap, folded and put into parcels of 25 forms each, and further put into packets of four parcels each; 250,000 leaves of forms for the "register of successful vaccination," made up into 5,000 books of 50 leaves each, with "examples" and "instructions" prefixed; 20,000 copies of the Compulsory Vaccination Act, 16 and 17 Victoria, cap. 100.

MEDICAL METEOROLOGY. The *Athenaeum* of September 10th, says: "Our attention has been drawn to a paper in the ASSOCIATION MEDICAL JOURNAL on Medical Meteorology. The object of the paper is to draw the attention of medical men to the importance of the registration of disease in connexion with the conditions of the atmosphere. We have often pointed out the present unsatisfactory method of generalising with regard to the influence of climate and weather on the results of disease. The only documents of any value for this purpose that we possess are those of the Registrar General, and they are far too vague to give anything like precision to the inferences that may be drawn from them. The following supposed case, from the paper alluded to, illustrates our remark: 'A patient was seized by an attack of bronchitis on the 7th of April in any year, and during the prevalence of a cold north-easterly wind; that the patient died on the 14th; and that on the 17th the death was registered; but meanwhile, that, on the 13th, the wind had changed to a mild south-westerly breeze; it is obvious that the registration of the death on the 17th could have no value as a medico-meteorological fact.' The facts that are wanted to be of value in such a case are, the dates of the first seizure and the state of the weather previous to that time. A moist and warm atmosphere, or a cold and dry one, may suddenly set in and terminate a number of cases which have been very variously commenced. In order to supply the information desired, the ASSOCIATION MEDICAL JOURNAL has undertaken to publish meteorological tables in connexion with the history of particular cases of disease. In this way we have no doubt that some important facts will be elicited. Already the physiologist is in possession of a large number of facts which show the influence of the great forces of nature on the life of the organic world; and the prosecution of this subject by the medical man, will be but the following out of these researches, and giving to us a more intimate knowledge of the laws which control the existence of organic beings on the earth."

WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON. In consequence of the reappearance of Epidemic Cholera, a special meeting of the Society will be held on Friday evening, October 7th, at 8 o'clock precisely, to consider the best method of investigating and treating the disease.

FIRE AT THE PRINTING OFFICE OF THE LANCET. The publication of our contemporary the *Lancet* was last week delayed for a day beyond the usual time, in consequence of the destruction by fire of the extensive printing establishment of Messrs. Savill and Edwards, Chandos Street, Strand, on the morning. The type of the *Lancet* was at the station when the fire broke out.

[The returns from DR. MOFFAT and MR. MILNER were not received in time for this Number.]

The readings of the Barometer are corrected for index-error and capillarity, and reduced to the constant temperature of 32° F.

The maximum observations for the day, Cols. 3 and 6, are taken after Three o'clock p.m. in the winter, and Six o'clock p.m. in the summer, and indicate the maximum temperature of the same day.

The minimum observations, Cols. 4 and 7, are taken at Nine o'clock a.m., and indicate the minimum temperature of the same day.

The mean temperature of the day, Col. 5, is deduced from the maximum and minimum readings in the shade.

The temperature of the dew-point, and degree of humidity, Cols. 8 and 9, are obtained from Glaisher's Hygrometrical Tables.

The force of the wind, Col. 11, is noted by figures from 0 to 6: the latter representing the highest wind, and 0 a calm; the letter V means that the wind was variable.

Arrangements for Ozone observations are not yet complete.

The amount of cloud, Col. 13, is noted by figures from 0 to 10: a cloudless sky 0, and a cloudy sky without sunshine 10.

The class of cloud is noted by ci. for cirrus; ci.-cu. for cirro-cumulus; ci.-s. for cirro-stratus; cu. for cumulus; cu.-s. for cumulo-stratus; n. for nimbus; and s. for stratus.

In Column 14, a. represents aurora; f. fog; fr. frost; hl. hail; l. lightning; lu. ha. lunar halo; sl. sleet; sn. snow; so. ha. solar halo; t. thunder; and z. zodiacal light.

The amount of rain is registered at Nine a.m., and has fallen during the previous twenty-four hours.

Columns 16 and 17 are devoted to diseases and deaths. Any disease or death, the precise date of the commencement or occurrence of which is known to the observer, is entered in the proper column, on the proper date of its occur

remc. The name of the disease alone indicates that one case of the disease had occurred; but if more than one case of the same disease had occurred on the same day, the figure indicates the number. The entries of diseases and of deaths do not indicate the extent of practice of the observers, inasmuch as those diseases only are entered the precise date of the commencement of which is known to the observer within the week; all other cases are rejected. The deaths are supplied (with the consent of the Registrar-General) by the Registrar of deaths for the district.

Abbreviations used when several cases occur, and have to be entered, on the same day:

Abo., indicates Abortion.
Ag., Ague.
Ap., Apoplexy.
Ang. Pec., Angina Pectoris.
At., Atrophy.
Br., Bronchitis.
Card., Carditis.
Ch., Cholera.
Col. + Vom., Colic with Vomiting.
Col. — Vom., Colic without Vomiting.
Conv., Convulsions in Children.
Cr., Croup.
Cyn. L., Cynanche Laryngea.
Cyn. Pa., Cynanche Parotidea.
Cyn. Ph., Cynanche Pharyngea.
Cyn. T., Cynanche Tonsillaris.
Cyn. Tr., Cynanche Trachealis.
Di., Diarrhoea.
Dys., Dysentery.
Ent., Enteritis.
Epi., Epilepsy.
Epi., Epistaxis.
Ery., Erysipelas.
Fe., Fever.
Hæmatem., Hæmatemesis.
Hæmatu., Hæmaturia.
Hæmop., Hæmoptysis.
Hem., Hemiplegia.
Hep., Hepatitis.
Hoop. C., Hooping Cough.

Inf., indicates Influenza.
Ins., Insanity.
Mea., Measles.
Men., Menorrhagia.
Mum., Mumps.
Ncu., Neuralgia.
Neph., Nephritis.
Oph., Ophthalmia.
Paral., Paralysis.
Parap., Paraplegia.
Phren., Phrenitis.
Plcu., Pleuritis.
Pu. Con., Puerperal Convulsions.
Pu. Fe., Puerperal Fever.
Pneu., Pneumonia.
Prem. L., Premature Labour.
Qu., Quinsy.
Ret. U., Retention of Urine.
Rub., Rubella.
Rh. Ac., Rheumatism, Acute.
Sc. Fe., Scarlet Fever.
Sci., Sciatica.
Sm. P., Small Pox.
T., Toothache.
Ty., Typhus.
Ut. Hæm., Uterine Hæmorrhage.
Var., Varicella.
Vario., Variola.
Vrr., Vertigo.
Vom., Vomiting.

NEWS AND TOPICS OF THE DAY.

[Continued from page 890.]

ROYAL FREE HOSPITAL MEDICAL COLLEGE. The introductory lecture at the opening of the first session of the new medical school in connexion with the Royal Free Hospital was delivered by Dr. Tyler Smith, at eight o'clock in the evening of Tuesday, the 4th instant. The subject which the lecturer chose as the theme of his discourse was the progress and influence of medical teaching, especially in this country. Having rapidly glanced at the probable origin of medicine as a profession in ancient Egypt, its progress in the hands of the Greeks, Romans, and Arabians, and having referred to the establishment of the first hospital at Constantinople in the early ages of Christianity, and to the institution of the first course of instruction and the first medical diploma at Salerno in Italy, he proceeded to occupy the greater part of the lecture with a history of the rise and progress of medical teaching in England. This did not commence with hospital authorities; for six centuries elapsed between the foundation of St. Bartholomew's Hospital by Rahere in the beginning of the twelve century, and the formation of the first medical schools in London. Most of the modern hospital medical schools originated either in the annexation of some private school which had excited the jealousy of the hospital authorities, or in the formation of a new school in opposition to some already existing private institution. Dr. Smith referred to the beneficial influence which medical teaching exercised both on teachers and students. The great discoveries of Harvey, Galvani, Jenner, and many others, had been made by them when acting in one or other of these capacities. With regard to the examining-boards, he believed that the merit due to them was not so much that of originating the modern movement in advance, as of arranging and combining the already existing elements. Teaching first made them important. The Apothecaries' Act of 1815, the prosperity of the College of Surgeons, and the establishment of the University of London, are effects of the great medical educational movement of the age.

In speaking of the College of Physicians, the lecturer regretted that the college had become to a certain extent separated from the currents of teaching, and trusted that with their new charter, they would become the superintendents of the education of all the physicians of this country. The East India Company's medical service had also partaken in the march of improvement. Formerly, favouritism and private influence had much to do with the distribution of the medical appointments, except in the case of a few which were from time to time placed at the disposal of various medical schools, to be given to the most deserving competitor; but by a new Act, which

will come into force next year, the medical appointments will be given only to candidates selected after examination. Dr. Smith then compared the London with the Parisian hospitals; contending that the schools of the metropolis had reached such a position, as to render London the capital of the medical world; and, having passed in review the improvements and enlargements in the London hospitals, either complete or now in progress, he concluded with some brief observations on the origin and progress of the Royal Free Hospital and its Medical College.

The lecture, which was attended by about two hundred students and members of the profession, elicited universal approbation. After the lecture, tea and coffee were provided in the reading room of the College. The museum was open for inspection, and was visited by many who had been present at the lecture. It appears to be well provided with anatomical and pathological preparations, and with specimens of articles of materia medica.

ROYAL COLLEGE OF SURGEONS. Mr. T. M. Stone, who has for many years ably performed the duties of Librarian, has been removed to another office in the College; and Mr. John Chatto has been appointed Librarian in his stead.

ADVERTISEMENTS.

East Surrey Cholera Society.—It is

proposed to form a Society for the observation of Cholera in East Surrey. Qualified Practitioners of Medicine willing to cooperate for this purpose are requested to communicate with the Provisional Committee.

B. W. RICHARDSON,

Hon. Sec. to the Prov. Committee.

A Report has been forwarded to every known Member of the Association; and it is earnestly hoped that this appeal on behalf of THEIR OWN Society will not be made in vain, to those whose duty as well as privilege it is to contribute.

Subscriptions will be thankfully received by the Treasurer, MR. NEWHAM; by the Honorary Secretaries, MR. NEWHAM and MR. TOYNBEE; or by any of the Committee.

Farnham, October 1, 1853.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLI.

LONDON: FRIDAY EVENING, OCTOBER 14, 1853.

NEW SERIES.

COMMUNICATIONS REGARDING CHOLERA AND LETTERS ON THE VACCINATION ACT IN OUR NEXT.

THE NUMERICAL STRENGTH OF THE ASSOCIATION IN OUR NEXT.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

THE FIRST PHYSIOLOGICAL MEETING IN LONDON.

THE first meeting that has ever taken place in London, for the purpose of debate on physiological subjects, was held on Monday last at the Medical Society. In this meeting was realised the scheme referred to in the Journal for February 18, and July 29; and we feel confident that all those gentlemen who have so long and so earnestly supported the scheme received a rich reward in thus witnessing a consummation of their untiring and not altogether thankful labours.

The report of the meeting will be found at another page. The rooms were well filled; and the discussion that took place was animated and interesting. Mr. LEE's paper could perhaps scarcely be called physiological in the strict sense of the word; it was rather a pathological subject illustrated by physiology; but we agree with Dr. LANKESTER, that physiological research is never so valuable as when it can be made to illustrate pathological questions. The success of John Hunter depended much, as we take it, upon his attempts at realising this position—attempts that gave to his works a practical bearing which none could resist.

Not the least interesting subject of the evening was the announcement by Dr. CRISP of the discovery of valves in the splenic veins of many animals. The preparations which he brought forward to prove the existence of these valves were exceedingly beautiful.

To pass to another matter:—we are desirous of answering once for all several inquiries that have been made to us by letter and word of mouth as to the relationship that exists between these physiological meetings and the Medical Society. The physiological meetings are a part of the Society itself. The Council elect twelve gentlemen, who are called the Physiological Committee. These gentlemen meet monthly, receive papers on physiological subjects, submit them to the necessary criticism, and make arrangements for their being read in public. The physiological meetings take place on the second Monday evenings of every month; the President of the Society presiding as usual. The papers that are read must either be written by a Fellow of the Society, or communicated through one. One paper is called the paper of the evening; but, before it comes on, there is a period given for the hearing of short communications on physiological points; and these brief communications, which often in similar meetings elicit a few minutes

of sharp discussion, are likely to prove highly interesting, and to deserve every possible encouragement.

A word more:—Is it not obvious to every unbiassed person that the Physiological Meeting of Monday evening was just as well conducted, in a scientific sense, as could have been the meeting of any special society? And does not the successful experiment to-day related prove satisfactorily the truth of a statement we have often made, viz., that one active society is competent to conduct, by means of sections, meetings connected with every department of medical science; and that to have several distinct societies where one is sufficient is a proceeding monstrously wasteful of money, and absolutely absurd?

ASSOCIATION INTELLIGENCE.

BATH AND BRISTOL BRANCH.

The Quarterly Meeting of this Branch was held at the York House, Bath, on the evening of September 29th, under the presidency of HENRY CLARK, Esq.

There were present:

Joseph Barratt, Esq. (Bath); J. S. Bartrum, Esq. (Bath); W. H. Brace, Esq. (Bath); — Chapman, Esq. (Devizes); Henry Clark, Esq. (Bristol) President; E. Cockey, Esq. (Frome); John Colthurst, Esq. (Clifton); James Crang, Esq. (Tisbury); W. Davies, M.D. (Bath); C. F. Edwards, Esq. (Bath); Farnham Flower, Esq. (Chilcompton); Gustavus Gidley, M.D. (Bath); James Godfrey, Esq. (Bristol); — Godfrey, Esq. (Bath); F. Hanham, Esq. (Bath); Henry Hensley, Esq. (Bath); W. B. Herapath, M.D. (Bristol); Edw. Hodges, M.D. (Bath); George King, Esq. (Bath); Joseph Lancaster, Esq. (Clifton); Joseph Lawrence, Esq. (Bath); Crosby Leonard, Esq. (Bristol); Frederick Mason, Esq. (Bath); E. S. Mayor, Esq. (Bristol); W. F. Morgan, Esq. (Bristol); George Norman, Esq. (Bath); John Ormond, Esq. (Bath); Joshua Parsons, Esq. (Beckington); G. Skinner, Esq. (Bath); Charles Smerdon, Esq. (Clifton); R. N. Stone, Esq. (Bath); J. G. Swayne, M.D. (Clifton); S. H. Swayne, Esq. (Bristol); John Thurnam, M.D. (Devizes); James Tunstall, M.D. (Bath); Thomas Washbourne, Esq. (Corsham).

DYSTOCIA FROM OSSIFIED FETAL HEAD. BY GEORGE KING, ESQ.

Mr. KING read a paper on the difficulty occasionally met with in labour, from abnormal ossification of the fetal head, and the treatment to be adopted. [This paper will be published in the JOURNAL.]

Dr. SWAYNE agreed with Mr. King upon the necessity of craniotomy in such cases. Abnormal ossification was a cause of protracted labour acknowledged by all practitioners. But he could not coincide with Mr. King's description of the difficulties attendant on the operation. In answer to a question by Dr. Herapath, he stated that, though no opportunity had yet presented itself for trying Dr. Simpson's plan of turning in preference to craniotomy, he quite felt that in many cases the former was the preferable mode. Mr. King had exaggerated the difficulty of perforating the cranium when the feet of the child had been brought down; though of course the difficulty was enhanced. Dr. Swayne exhibited two fetal crania, illustrating the very different sizes and conditions at birth.

Dr. HERAPATH had turned in three cases where otherwise craniotomy would have been requisite. In the first case, the pelvis was deformed; the brim was contracted, and the promontory of the sacrum thrown forward. In the previous labour, craniotomy had been performed. When he saw the woman, the passage through the pelvis had been long delayed; but there was not the difficulty in turning which he had expected. In about half an hour he succeeded in bringing down the feet, but

the child was dead. In the second case, where otherwise the child must have been destroyed, he turned it, and it was born alive. During his studentship he had attended a case which had not made a due impression on his mind. The woman's first child had been destroyed; but on this occasion the feet presented, and the child passed into the world without much difficulty.

The PRESIDENT drew attention to the peculiar point of Mr. King's paper. He (the President) had attended hundreds of cases, but had never lost a case from the child's head being the cause of its non-descent into the pelvis; and he felt sure that ossification of the fetal skull was very rarely indeed so extreme as to prevent the descent into ordinary, not of course into contracted pelves. In these latter cases there is no other step than craniotomy. There may be difficulties in the diagnosis; but when the practitioner has decided on his course, there is need of the utmost care that the soft parts are not lacerated by the descent of the cranial bones. When a portion of the cranium has been seized by the craniotomy forceps, the circle of the head necessarily becomes flattened, the bones diverge, and without care the soft parts may be injured.

Mr. KING stated that probably the two patients mentioned in his paper had some peculiar tendency to form highly ossified crania in their fetuses; as in these two he had chiefly noticed the phenomena detailed. As regarded the use of the forceps which he exhibited, the fetal bones were first to be broken down, then the forceps were to be carefully inserted between the neck of the uterus and the cranium.

THE DISCOVERY OF QUININE AND QUINIDINE IN THE URINE OF PATIENTS UNDER TREATMENT WITH THE SALTS OF THESE MIXED ALKALOIDS. BY W. B. HERAPATH, M.D.

Dr. HERAPATH described an application of a test for quinine and quinidine (which he had detailed in the *Philos. Mag.* for September), to the determination of these alkaloids in the animal fluids, especially in the urine. To eliminate the alkaloid, Dr. Herapath having recourse to the capital process of Stas,* founded on the capacity of ether for abstracting a *free alkaloid* from its aqueous solution, directs the clear liquid to be treated with slight excess of liquor potassæ, and subsequent agitation with ether. The ethereal solution will contain the quina or its analogue, if either or both be present.

To test this solution, it must be evaporated to dryness in a warm place, and to one drop of a mixture of acetic acid 3 iij, sp. rect. f. 3j, and dilute sulphuric acid ℥vj, a minute portion of this residue is to be added; and when solution has been effected, a drop of a dilute alcoholic solution of iodine. At first, if the residue be, or contain, quina, the brownish compound containing iodine and quina is obtained, which gradually changes into the very pretty green-pink polarising crystals which Dr. Herapath has called "sulphate of iodo-quina". Under the microscope, employing the selenite stage and single tourmaline, these crystals exhibit the respective complementary colours, red and green, when the pink stage is employed; blue and yellow with the blue stage.

For quinidine the author recommends a drop of the acid solution, as obtained above, previously to adding the tincture of iodine, to be suffered to evaporate to dryness on the glass slide, when the crystalline mass is to be examined by two tourmalines, crossed at right angles, but without the selenitic stage; when little circular disks of white, with a well defined black cross radiating from the centre, are perceived, if even minute traces of quinidine be present. With the selenitic stage, the black cross is replaced by one of great beauty, exhibiting a red and green fringe, the four intermediate sections being a bright orange, altering in tint according to the position of the analysing plate.

From the examination of the urine of a patient taking 40 grs. of quina disulph. daily, 1 4-10 gr. of quina were obtained from f. 3viij of urine, which is equal to about one-fourth of the quantity administered. We gather from a perusal of this communication that both the alkaloids in question were detected in this urine, but we are left somewhat in doubt as to the presence of quinidine. Satisfactory proof, however, is given of the passage of a portion of the quina salt through the system without the alkaloid undergoing any change; the paper closing with alluding to the probability of our being able, by means of this elegant test, hereafter to determine the *medical equivalent* of quina in a given disease.

The PRESIDENT observed that there could be no doubt as to the elimination through the kidneys of quinine. But what were the practical results of such investigations? Are we to give specific doses for specific diseases? If so, in each disease we

must endeavour to ascertain the appropriate dose; for in some diseases, patients will bear more of this remedy than in others, what is not required by the system being eliminated, partly through the kidneys. In a case of tetanus referred to, a large proportion of the remedy was thus eliminated; more having been taken than was required. By the term "toleration of a remedy", he meant that the system would take up a quantity of the remedy without disturbance; the superfluous portion then passing off by various excretory organs. He expressed his sense of the value of Dr. Herapath's investigations.

Dr. DAVIES called attention to the number of substances which we were accustomed to recognise as being eliminated by the kidneys; as the odour of asparagus, turpentine, copaiba, etc. When resident in the fever wards in Edinburgh, he had been much struck by the following facts. While in good health, after being some hours in the wards, he noticed at night that his urine possessed that odour so peculiar to fever. This he noticed for some months. By degrees, as his own health became feeble, and his system affected by fever poison, the odour lessened, till at length it ceased altogether on his being laid up by an attack of fever. This had convinced his own mind that a poison of so peculiar a character could be taken and thrown off by the system while vigorous, but that it was appropriated by it when weak, and at length the seed thus sown sprang into disease.

CASE OF FRACTURE OF THE CRANIUM IN AN INFANT AT BIRTH.

BY J. G. SWAYNE, M.D.

[This case is published at p. 901 of the present number.]

Mr. KING suggested that probably the child's cranium was more bony than usual, otherwise a fracture of the parietal bone could scarcely have occurred. Did the child die from the blood effused beneath the cranium?

Dr. TUNSTALL observed that such cases showed the absolute necessity for medical evidence before the coroner. Suppose this child had been illegitimate, or no one had been present, the mother might have been committed for manslaughter, and the judge would have said that medical evidence was imperatively required. In another case, a man who had been for some time ill, had died of hæmoptysis, of which he (Dr. Tunstall) gave a certificate. The neighbours then talked about the case, and an inquest was held. The jury brought in a verdict in the words of his certificate, without calling medical evidence.

Mr. HENSLEY asked if in such a case Dr. Swayne was entitled to make a *post mortem* examination, without giving the coroner notice of the accident to the child. He mentioned the following circumstance. A child had for a long time suffered from hydrocephalus: in the street, another accidentally run against it and knocked it down. Immediately, a clear colourless fluid, to the amount of a pint, oozed from its ears, with great relief, and the child got well. After a fortnight, the fluid reaccumulated, more active symptoms came on, and the child died. A *post mortem* examination was made, and a certificate was given that the child had died of disease of the brain. After a time, the coroner's man got scent of the case, and called on Mr. Hensley, stating that he had heard that the child had died after a fall. The coroner was informed by Mr. H. that the child's death was not dependent on the fall. However, he was not satisfied: he wrote to Mr. H. some most offensive letters, and at last had the child exhumed, that an inquest might be held. Mr. Hensley mentioned this case, to elicit from those acquainted with the rule, what course ought to be adopted by a medical man in such circumstances.

Dr. SWAYNE had certified that the death arose from a fall on the head leading to convulsions induced by the extravasation within the cranium.

Mr. WASHBOURNE mentioned several instances where the county magistrates had refused the coroner's fees, in cases of death either sudden or open to suspicion. This made the coroners very reluctant to call in medical evidence where they can possibly do without it.

Mr. STONE observed that medical men were too apt to give their labour gratuitously, consequently coroners and juries were only too happy to avail themselves of their unpaid services.

Mr. NORMAN said that, in cases of any doubt, medical men should not give any certificate till after the inquest was over. The object of the certificate was for the purposes of burial, as far as the public was concerned.

Dr. DAVEY would draw the attention of the meeting to the physiological points of such cases. In this case convulsions did not come on till the sixth day. Were these dependent on the injury to the brain? They were. Mr. Guthrie's experiments had shown that convulsions did not come on till three or four days after the injury. They do not seem dependent on the pressure of the brain or spinal irritation, but convulsions follow the inflammatory symptoms, because the inflammation

* This we shall have occasion to describe in an early number. EDITOR.

the brain and spinal chord has been disturbed. Cases of this kind present physiological and pathological phenomena of great interest.

INSTRUMENT FOR PARACENTESIS THORACIS. BY HENRY CLARK, ESQ.

The PRESIDENT exhibited an instrument which he had made for drawing fluid from the pleura by an exhausted receiver, and so preventing the entrance of air.

[A description and drawing will be published in the JOURNAL.]

Dr. HERAPATH had recently a patient with paracentesis abdominis, in a state of extreme exhaustion. He had removed the fluid by passing the tube of a stomach pump into the pelvic portion of the peritoneal cavity, while the patient was recumbent, and had thus drawn off all the water. The patient recovered. In another case, where similar means were used, the amount of fluid was not so great, but the disease was complicated with ovarian tumour. The fluid was removed successfully, and the patient then went into the infirmary. The ovarian tumour opened itself through the rectum, and thus the woman was cured.

Mr. HENSLEY and Mr. NORMAN detailed cases where an instrument like that exhibited would have been most useful.

Thanks having been voted to the authors of the communications and to the Chairman, the meeting broke up.

ORIGINAL COMMUNICATIONS.

FACTS AND OPINIONS RELATING TO TUBERCULOSIS, WITH COMMENTARIES.

By HENRY ANCELL, Surgeon.

NO. II.

MANY of the readers of the ASSOCIATION JOURNAL may not have the opportunity of referring to the original *Statistical Reports of the Sickness, Mortality, and Invaliding, among the Troops*; and it may be well to point out a few particulars illustrating the degree of accuracy attributable to them. The first and most important point is, that, by a standing order of the army authorities, a *post mortem* examination is required to be made in every case; and this rule is deviated from in the fewest instances possible. The sources of error are the usual ones of mistaken diagnosis and nosological imperfections. As soon as a man becomes seriously ill with chronic disease, he is invalided; and among those cases reported under "chronic catarrh," "hepatitis," and other designations, some may ultimately prove to be cases of phthisis. Again, among those invalided and discharged from the service, merging into the civil population, returns are not obtained of the ultimate results, or the causes of death. The consequence of these circumstances, *pro* and *con*, is, that the numbers representing the frequency of death from phthisis are always to be regarded as the *minima* of the actual occurrence of the disease. As respects the numbers representing the admissions, it must also be borne in mind, that the same cases, having been discharged cured or relieved, may be readmitted, when they are regarded as new cases; and the proportion of deaths to the admissions must not be taken absolutely, inasmuch as the difference between them is, to a great extent, made up of these readmissions. With the latter qualification, phthisis is a much more fatal disease than it would otherwise appear to be. Since these circumstances appertain to the whole series of the army statistics, they do not invalidate the comparison of one part with another; and, provided we bear in mind the sources of fallacy, and avoid adopting the numbers as positive mathematical data, they afford a most useful means of comparison with other statistical results. In such of the tables as I have worked out myself, I have, in most instances, omitted decimal fractions, since it is only where very decided differences exist that we can arrive at conclusions from such data.

The medical statistics of the British troops serving in the three Mediterranean commands, Gibraltar, Malta, and the Ionian Islands, during the sixteen years included in the report now under review, as compared with the statistics of

the previous twenty years contained in the former reports, indicate but little amelioration in pulmonary diseases in the aggregate, and none as respects tuberculosis; for, although, as seen in the following tables, the proportion of deaths to the amount of the force employed is, in some instances, diminished, the authors very justly attribute this circumstance, in the main, to the increased facilities for sending invalids home, since the establishment of regular steam communication with England, and the unavoidable omission of the results, where the individuals have been discharged the service.

The aggregate strength in the above commands, during the ten years, was 80,504 British troops, and 3,453 Malta fencibles, or natives of the island enlisted for ten years; in all, 83,957. For the reasons stated in the last paper, hydrocephalus is a rare occurrence, one case only being recorded; and tabes mesenterica is not mentioned. The number of cases of *scrofula* admitted into hospital among the British troops was 247, and among the Maltese troops 2; the proportions of admissions and deaths to the aggregate strength were as follows:—

	Strength.	Admission.	Deaths.
Gibraltar.....	33131	1 in 315	1 in 16565
Malta	21172	1 in 282	None.
Malta Fencibles..	3453	1 in 1726	None.
Ionian Islands	26201	1 in 391	1 in 26201

The number of cases admitted into hospital for *scrofula*, among the troops serving in the Mediterranean, was thus a small fraction over 3 per 1,000; while, among those serving at home, as shown in my first paper, it was 4 per 1,000.

Our next point is the aggregate amount of pulmonary disease, represented in

TABLE V.

The proportionate number of pulmonary diseases to the amount of the force, in the troops serving in the Mediterranean commands.

	Aggregate strength, 10 years.	Annual ratio per 1000.	
		Admitted.	Died.
Gibraltar.....	33131	132.	5.82
Malta	21172	140.	7.93
Malta Fencibles (Natives)	5547	23.8	3.8
Ionian Islands	26201	134.	0.22
Corfu and Vido	10063	145.	6.1
Paxo	413	75.	2.4
Santa Maura	1254	89.	.8
Cephalonia	3509	114.	5.3
Zante	2904	127.	4.6
Ithaca	571	117.	3.5
Cerigo	510	145.	3.9

This table comprises not only the deaths in the military hospitals abroad, but also the deaths, whether during the voyage or at Chatham, of troops invalided and sent home; but it does not represent the whole mortality, since the deaths after discharge from the service, as before stated, are not included.

In Gibraltar, from the year 1818 to 1836, the admissions and deaths per 1,000 mean strength, were respectively 142 and 5.5; the latter number not including the deaths among those invalided and sent home. In Malta, from 1817 to 1836, also omitting the deaths among invalids, the ratios were, respectively, 120 and 6 per 1,000. This shows for Gibraltar a rather considerable diminution both of admissions and deaths, compared with the numbers for the last ten years; for Malta, a considerable increase of admissions, the excess arising from the greater number of cases of acute catarrh, which prevailed in 1837, 1840, and 1841: and a slight diminution of deaths, as seen more clearly in the next table.

We have now to look to the relative proportions of each specified disease of the lungs contributing to the sum total of pulmonary sickness and mortality.

TABLE VI.

Specification of pulmonary diseases among the troops in the Mediterranean, with the number of admissions into hospital, and deaths, during ten years, from 1837 to 1846.

	Gibraltar, 33,131.			Malta, 21,172.			Malta Fencibles, 3,453.			Ionian Islands, 26,201.		
	Admitted.	Died.	Deaths to Admissions.	Admitted.	Died.	Deaths to Admissions.	Admitted.	Died.	Deaths to Admissions.	Admitted.	Died.	Deaths to Admissions.
Pneumonia	333	20	1 in 16½	287	6	1 in 48	1	—	—	232	16	1 in 15
Pleuritis	158	2	1 in 79	22	—	0 in 22	1	—	—	33	1	1 in 33
Hæmoptysis	78	1	1 in 78	70	1	1 in 70	5	3	3 in 5	57	2	1 in 28½
Phthisis	176	116	2 in 3	129	91	2 in 3	7	6	6 in 7	145	89	1 in 1½
Acute catarrh	3027	3	1 in 1009	2009	11	1 in 183	52	1	1 in 52	2392	8	1 in 299
Chronic catarrh	525	8	1 in 66	303	16	1 in 25	10	2	1 in 5	588	18	1 in 32
Asthma	44	1	1 in 44	0	1	1 in 9	5	—	—	11	1	1 in 11
Difficulty of breathing..	31		None.	40			1	1	1 in 1	49	5	1 in 9
Pertussis	1		None.									
Total	4373	151	1 in 29	2908	126	1 in 24	82	13	1 in 6.3	3507	140	1 in 25
Annual ratio per 1000, mean strength	132	4.56		140	5.95		23.7	3.7		194	5.3	
Ditto, including deaths of invalids		5.82			7.93							

An important remark is made by the authors of the report, that the diminished mortality at Gibraltar during the last ten years is due, altogether, to a diminished number of deaths from inflammatory affections, and not at all to a smaller amount of tuberculosis pulmonalis; in illustration of which, they furnish the following ratios:—

	Deaths per 1000 mean strength.	
	1818 to 1836.	1837 to 1846.
Inflammation of the lungs93	.60
Catarrh65	.33
Consumption and hæmoptysis....	3.70	3.62

At Malta, also, the mortality from inflammatory diseases, during the last ten years, was only about two-thirds that of the previous twenty years; whereas, from consumption, it is represented by numbers almost identical. The mortality from pulmonary diseases in the aggregate was greater among the troops serving at Malta than among those serving in the Ionian Islands, in the proportion of about 8 to 6, although the climate of the former is much milder, and cold winds and sudden alternations of temperature are comparatively rare.

At Gibraltar, a special cause of improvement of the health of the force existed. In addition to the ordinary duties of a peace establishment, working parties were furnished, in considerable numbers, to assist in improving the fortifications; and the comparative immunity from disease enjoyed by these parties was often a subject of observation.

Comparing the amount of pulmonary disease, as measured by the admissions into hospital, among the troops serving in the United Kingdom, with the amount among those serving in the Mediterranean (Tables III, IV, V), it is found to be considerably greater in the former than in the latter. Comparing the number of deaths, the ratio per 1,000 is considerably less for Gibraltar, but greater for Malta, than among the dragoon guards and dragoons serving at home; it is less in Malta than among the infantry at home, by about 2 per 1,000.

This brings us to the more particular consideration of the amount of *tuberculosis pulmonalis* among the troops in the Mediterranean. The cases of phthisis in the different commands were as follows:—

	Admissions.	Deaths.
Gibraltar	1 in 188	1 in 285
Malta	1 in 164	1 in 232
Malta Fencibles	1 in 493	1 in 575
Ionian Islands	1 in 180	1 in 294

On reducing this to a mean of the three commands, the proportion of deaths from phthisis, in the British troops serving in the Mediterranean, is 1 in 271, being below the mortality among the male population at home at the period

for military service, and less than half the mortality among the military at home; but, unfortunately, for the reasons before assigned, the above numbers represent the minimum of deaths, and by no means the whole mortality from this disease.

In the Malta Fencibles, or native troops, with an aggregate strength of 3,453, during six years, the annual ratio per 1,000 admitted into hospital for diseases of the lungs was 23.8, and the annual deaths 3.8. Of a total of twenty-eight deaths, thirteen, or nearly one-half, were from pulmonary disease. Of twelve admissions for hæmoptysis and consumption, nine died, and there is no certainty of the others having recovered; so that, although they were considerably less liable to phthisis than the British troops, when attacked, the disease proved equally, if not more certainly, fatal.

Having thus shown the frequency and fatality of pulmonary affections, and particularly of phthisis pulmonalis, among soldiers in these various commands, the report refers to the liability of sailors to the same class of diseases while serving at the home and the Mediterranean stations. The data for the following table are extracted from the Navy Reports:—

TABLE VII.

Comparison of the sickness and mortality from pulmonary diseases in the naval and military forces in the Mediterranean.

	In the naval force: out of an aggregate of 100,464.		In the military force: out of an aggregate of 102,214.	
	Attacked.	Died.	Attacked.	Died.
Pneumonia and pleurisy	2598	86	2281	.92
Hæmoptysis	234	12	269	8
Phthisis	437	180	629	419
Catarrh	21971	27	11314	83
Asthma and dyspnoea ..	161	7	213	6
Total	25401	312	14706	606
Ratio per 1000 mean strength	258	3.1	144	5.9

The attacks of pulmonary diseases, viewed as a class, are thus nearly twice as numerous in the navy as in the army. The proportions, however, both of attacks and deaths, as regards inflammation of the lungs, pleurisy, and hæmoptysis, are almost identical in the two services; the difference being determined chiefly by catarrh and consumption, in reference to these two diseases, a very small difference appears. While the cases of catarrh are

in the navy as in the army, those of consumption are less, in the proportion of four and three-tenths to six and one-tenth. This fact, as well as the low number representing the deaths from these diseases in the navy, is considered to be, in part only, attributable to the facility for sending home all cases which begin to assume a serious character.

The following table is also given in the Report :—

TABLE VIII.

The proportionate numbers of the naval force attacked by consumption and hæmoptysis, on the Home and Mediterranean stations, during seven years, from 1830 to 1836 inclusive.

	Aggregate strength, 7 years.	Cases of consumption and hæmoptysis.	Ratio per 1000, mean strength.
Home Force	21493	174	8.10
Various Force*	16250	120	7.94
Mediterranean Command	55709	482	7.75

These tables furnish conclusive evidence of two things; that neither the climates nor the seafaring life exert any decided influence in preventing or retarding the development of consumption; for although, in the navy, only two-fifths of those reported as consumption appear to have terminated fatally (Table VII), the remainder must not be considered as having recovered. Many, no doubt, died after their return home and discharge from the service. At the same time, the reporters remark, that either the air or the excitement produced by the voyage appears sometimes to mitigate the symptoms, as in the case of soldiers sent home from Malta, apparently labouring under confirmed phthisis; who have sometimes arrived home with renovated health, and speedily returned to their duty.

Having given the statistical facts relating to tuberculosis among the troops serving at home and in the Mediterranean, I now proceed, in the same order, with the returns from British America. This includes four military com-

mands, viz., the Bermudas; Nova Scotia, New Brunswick, etc.; Canada; and Newfoundland. The latitude and climate of the Bermudas differ so greatly from those of other stations, that it will be necessary in most instances to treat of them separately. The aggregate strength in these islands, during the ten years, was 11,224, and in the remaining commands 120,989. As in Great Britain and in the Mediterranean, hydrocephalus and tabes mesenterica are extremely rare occurrences; they are not mentioned in the report from the Bermudas; and there were but two cases of the former, with two deaths, in the remaining commands. Of *scrofula*, there were 48 cases in the Bermudas, and an aggregate of 169 in North America, which numbers furnish the following proportions :—

	Strength.	Admissions.	Deaths.
The Bermudas	11,224	1 in 238	None.
Nova Scotia, New Brunswick, etc.	26,806	1 in 348	None.
Canada	90,456	1 in 1,016	1 in 30,152.
Newfoundland	3,727	1 in 1,242	None.

We now turn to pulmonary affections.

TABLE IX.

The proportionate number of pulmonary diseases to the amount of the force, in the troops serving in the various commands in British America.

	Aggregate strength, 10 years.	Diseases of the lungs. Annual ratio per 1000.	
		Admitted into hospital.	Deaths, including invalids.
The Bermudas	11224	134	9.4
Nova Scotia, New Brunswick, etc. ... }	26806	180	7.7
Canada	90456	157	7.44
Newfoundland	3727	190	4.3

The particular diseases which furnish these proportions are as follows :—

TABLE X.

Specification of Pulmonary Diseases among the Troops in British America, with the number of admissions into Hospital, and deaths, during ten years, from 1837 to 1846.

Annual ratio per 1000, strength	134	8.3		180	7.1		157	6.57		109	4.3	
Ditto, including deaths of invalids		9.4			7.7			7.44				

The proportion of consumption to the aggregate force, deduced from the last table, is as follows :—

	Admissions.	Deaths.
Bermudas	1 in 112	1 in 207
Nova Scotia, New Brunswick, etc. ...	1 in 179	1 in 241
Canada	1 in 172	1 in 276
Newfoundland	1 in 248	1 in 286

* The term "various" applies to ships, though reckoned on home service, employed occasionally abroad in various detached duties.

Thus, in Canada and Newfoundland, during these ten years, the proportionate number of deaths from phthisis was below that of the male population of England at the period of life for military service. In Nova Scotia, New Brunswick, etc., the proportion, during the year 1847, adopted in these papers for the purpose of comparison, was a very little above that of the male population at home from 15 to 50 years of age, and considerably less than that of the male population from 20 to 40 years of age. In Bermudas, the proportion was much greater than among the

civil population, and the dragoon guards and dragoons at home, and not much below the infantry of the line and the foot guards.

In the study of these statistics, then, the first, and one of the most important questions which presents itself, relates to the influence of migration to these widely different climates over the production or development of tuberculosis. We find that, contrary to the popular, and I may say, the professional view, migration to a warm climate afforded very little amelioration in any case except one, but in some cases an aggravation; and migration to a cold climate, instead of increasing, actually diminished the amount of this fatal disease. The cases admitted, and the deaths from consumption, were considerably less in number in the rigid northerly climates of Canada, Nova Scotia, and Newfoundland, than in Bermuda and Malta. This is shown again most unequivocally in the following:—

TABLE XI.

Comparison of deaths from consumption and hæmoptysis in Malta and Canada.

1837—46.	Aggregate strength.	Admitted for consumption and hæmoptysis.	Died of these diseases.	Ratio per 1000 mean strength.	
				Admitted.	Died.
Malta.....	21172	208	92	9.8	4.3
Canada	90456	760	345	8.4	3.8

The statistics of the invalids discharged the service, on account of pulmonary disease, are, upon the whole, confirmatory of the same facts, as shown by the following proportion per 1,000 mean strength:—

Gibraltar	5.1	Canada	5.2
Malta	4.6	Nova Scotia, etc.,...	4.6
Ionian Islands	4.3	Bermudas	5.

Thus, the number invalided for pulmonary diseases, in the aggregate, is almost the same in Gibraltar, where the temperature ranges from 45° to 86°, as in Canada, where it ranges from 23° below to 87° above zero; and, whether we take as our criterion the number admitted into hospital,

the number of deaths, or the number invalided, there is less consumption in the British army in the northern climates than at home, in the Mediterranean, or in the Bermudas.

It is indeed one of the most remarkable circumstances, that, throughout the thirty years over which these and the statistics formerly published extend, the mortality from diseases of the lungs, and especially from tuberculosis pulmonalis, in the mild and comparatively equable climate of Bermuda, is much higher than in the North American colonies, with their extremes of heat and cold, and their long continued winters. That this circumstance is not accidental, we have a proof in the length of the period, and the uniformity of the results; and, also, in the fact that, by the statistics of the United States army, in East Florida, which is in nearly the same latitude as Bermuda, with a corresponding temperature, the admissions into hospital for consumption are much more numerous than in the northern regions. In Florida, they amount to eight and seven-tenths per 1,000 mean strength annually; while in the countries beyond the 40th degree of north latitude, including all those where the winter is most severe, the proportion admitted for the same disease is only seven per 1,000. Newfoundland has a climate more liable to sudden vicissitudes than any part of the American continent to which British troops are sent, and is subject to frequent and dense fogs throughout the year; and, as remarked by the authors of the Report, the small number of deaths from consumption affords another striking instance how little this disease appears to be influenced by those atmospheric causes which were at one time supposed to be most active in its production. The proportion of the whole force attacked annually was about four per 1,000; in the Mediterranean, out of an equal number, the proportion would have been five and six-tenths; among the infantry in the United Kingdom, ten and three-tenths; and in the mild and comparatively equable climate of Bermuda, nine per 1,000 mean strength.

For the purpose of affording every facility for comparison to those who interest themselves in these matters, I have drawn up the following more complete table, in three parts, of the proportionate numbers of the admissions, and the deaths from each disease of the lungs, to the number of the troops in every command:—

Before we dismiss the facts relating to climate, it is worthy of note, that of all the localities embraced in this report, in which British troops serve—at home, in the Mediterranean, or in Canada,—the most marked immunity from the production or development of consumption, and other pulmonary affections, belongs to Santa Maura, which is the

exception to which I have already referred. In further illustration of this, the following table, copied from the report, furnishes a comparative view, according to another mode of grouping, of the frequency of these affections in the island in question, and in three other Mediterranean stations.

Only five admissions for phthisis and hæmoptysis, and not one death, among 1254 individuals, or a mean force of 125, occurred throughout ten years; and according to previous reports there were only three admissions in fifteen years. Had this immunity been confined to *deaths* from phthisis and other chronic diseases, the reporters state, that they might have been disposed to attribute it to several of the cases having been sent to Corfu, but it is manifested in the acute form, and more especially in the *admissions*; they further remark, "that this is not an accidental circumstance depending upon the irregularities which occasionally arise from the smallness of the numbers under observation, may be inferred from the peculiarity having occurred during the previous twenty years, when the mortality by this class of disease was scarcely half as high as in any of the other islands".

These circumstances render the question of the topography of the island highly interesting, not to say important, and I know no better source of information than Colonel Tulloch's former report. Santa Maura is about twenty-three miles long by ten broad, situated 39° N. Lat. 20° 30' E. Long., and about a hundred yards from the mainland of Greece. It has a chain of mountains running north and south through its whole extent, and rising in some places to 3000 feet, with secondary ridges intersecting the island in various directions. The soil is alluvial, or a rich loamy earth, tenacious of moisture, generally very scanty, the surface exhibiting to view a large proportion of bare rock interspersed with small patches of verdure. There are no rivers, but torrents flow from the mountains during the winter months, converting some of the valleys into lakes and marshes during the rainy season. The temperature is extremely variable, its annual average about 65½°, seldom falling to the freezing point in the low grounds, but occasionally there is snow on the hills. The range of the thermometer in autumn sometimes exceeds 20° in twenty-four hours. The quantity of rain and the seasons in which it falls are much the same as in the Ionian Islands generally, in which the mean of nine years was 44.86 inches. Like the rest of the Ionian Islands, it does not appear to possess any immunity from extremes of dryness and moisture, and of tempestuous and calm weather, which often succeed each other in a few hours; it is extremely liable also to mists and

rain with the south winds, and is subject to earthquakes sometimes continuing without intermission for several weeks. When the wind blows from the snow-capped hills the sensation of cold is said to be experienced as strongly as in more northern latitudes. There is only one fresh water lake of any extent, about six miles to the south of the town, in the bottom of a valley surrounded by high mountains, which becomes dry in summer, and the soil produces rich crops. The principal fortress, with the barracks, is far from being favourably situated, as this stands on a low narrow strip of land close to a shallow muddy lagoon. The troops have no duty to perform beyond the ordinary guards, which do not come round oftener than about once in five days. Owing to the low price of wine and spirit the facilities for intoxication are very great, and in none of the islands have so many cases of *delirium tremens* occurred. The prevalent diseases, both among the troops and the natives, are fevers, continued, remittent, and intermittent, but particularly remittent fever, and the experience of this island tends to support the conclusion that tuberculosis pulmonalis is less common in low marshy situations where these fevers prevail.

This description, taken with the fact of the long continued comparative immunity of the troops from tuberculosis, is extremely interesting. It is only to be regretted that the numbers are not larger, so as to inspire more confidence in the result. It is suggested in the report, as worthy of consideration, whether a sanatorium for soldiers labouring under chronic diseases of the lungs might not be established there with advantage, for the whole command. Considering the present state of the question respecting the influence of climate over tuberculous diseases, I should say that, even as an experiment only, this would be most desirable.

The statistical reports before us furnish some new facts by which we may estimate the influence exercised by season over tuberculous diseases. In my work, I have shown from a variety of records, that contrary to the general opinion, the season of the year appears to have little or no relation, as a cause, to tuberculosis pulmonalis. (On *Tuberculosis* p. 507). This result was arrived at from data contained in the tables of the Registrar General, and the Army Reports previously published; and in the recorded in-

vestigations of the point by Louis and other individuals. From these documents, it appeared that neither the occurrence of phthisis, nor the mortality, is materially greater or less in spring, summer, autumn or winter, in any of the countries where the disease prevails. The statistics before us are, upon the whole, confirmatory of this view. By the first table of the present series of papers, the deaths from tuberculosis returned to the Registrar General during October, November, December, January, February and March, were 4,867; and during April, May, June, July, August, September and October, 5,008. The deaths from phthisis during the same periods, were, respectively, 3,473, and 3,462; although, taking the latter disease alone, there is a slight excess in the earlier months of the year, thus:—

For the Quarter ending March 27	1,811
" " June 26	1,790
" " Sept. 25	1,672
" " Dec. 25	1,662

In exemplification of the same subject, the following table is drawn from the Army Reports. On examining its details, there is, perhaps, as remarked in the report, no cause of surprise at the uniformity of the results in the Mediterranean commands, where the climate is, comparatively, so little variable according to the season of the year, but if we had not been apprised of it by the facts detailed in the former reports, the case, as respects British America, would be otherwise.

In the first place, the ratio per 1000 in hospital with pulmonary diseases, in Great Britain, on the first day of the month, during ten years, was as follows:—

January	8.1	July	5.6
February	8.6	August	4.8
March	8.2	September	5.3
April	7.2	October	5.2
May	6.7	November	5.8
June	5.4	December	6.7

TABLE XIV.

The Number of Admissions into Hospital, and Deaths from Pulmonary Diseases, in every Month throughout the Year, among the Troops serving in the Mediterranean and in British America.

	MEDITERRANEAN.								BRITISH AMERICA.							
	Gibraltar.		Malta.		Ionian Isles.		Total.		Bermuda.		Nova Scotia and New Brunswick.		Canada.		Total.

April . . .	294	9	221	14	273	13	788	36	135	8	302	16	1215	60	1607	76
May . . .	336	11	202	9	300	13	838	33	131	3	357	12	1172	48	1549	60
June . . .	315	7	212	5	244	7	771	19	100	3	339	14	961	40	1300	54
July . . .	304	3	182	6	214	3	700	12	94	6	304	13	1200	36	1513	49
August . . .	289	4	205	9	211	11	705	24	149	7	279	12	974	39	1255	51
September . .	283	8	197	5	237	10	717	23	104	6	248	8	812	39	1060	47
October . . .	279	10	259	10	218	11	756	31	123	10	298	7	1058	29	1356	36
November . .	188	13	224	16	193	9	605	38	96	6	335	6	1094	33	1429	39
December . .	317	11	217	13	271	13	805	37	97	7	405	10	1212	51	1617	61

Although, in Great Britain, pulmonary diseases as a class, among the troops, are at their minimum between July and October, the difference, as compared with the coldest months, in the number under treatment, is only as 5 to 8. In Canada, there is a larger proportion of deaths from December to April; but, on analysing the causes of death, it appears that 124 of the total number resulted from pneumonia, and 327 from phthisis, and since, in all probability, although it is not stated in the report, death from pneumonia was most frequent during the severe season, this would make up the difference, and leave phthisis as fatal at one season as at another. In the Bermudas, where there were only four deaths from pneumonia, there is no marked difference in the mortality in the cold as compared with the warm season.

Taking diseases of the lungs, in the aggregate, the slight differences which exist between the proportions of cases occurring during the summer and winter quarters, in North America, are shown by the following reduced table of the numbers attacked:—

TABLE XV.

	Canada.	Nova Scotia and New Brunswick.	Bermuda.
First Quarter	3805	1050	368
Second Quarter	3348	1088	366
Third Quarter	2995	831	347
Fourth Quarter	3364	1038	316

Thus, in Canada, the excess of cases in the first quarter of the year when the weather is "most severe", we may say intense, is only one fourth more than between July and September; and in Nova Scotia the only difference of any importance is about one-fifth in favour of the quarter from July to September. The mean temperature between this

quarter and the one which precedes it, differed about 40°, being to that extent warmer; but the quarter ending June 30th, which is much warmer than either of the two that precede it, presents absolutely the most cases of pulmonary disease. At all events, we have no evidence that the season of the year exercises any uniform influence, over the production of tuberculosis, in promoting its development as a disease of the lungs, or in hastening or increasing its fatality.

TABLE XVI.

The number of cases of pneumonia with the proportion of deaths and recoveries, and the number of admissions into hospital for phthisis among the troops in the United Kingdom, the Mediterranean and British America, and in the aggregates of the naval and military forces serving in the Mediterranean.

	Pneumo.	Died.	Recovered.	Phthisis.
United Kingdom:				
Dragoon guards & dragns.	337	24	313	386
Foot guards	539	42	497	654
Infantry of the line . . .	1897	155	1742	1657
Gibraltar	333	20	313	176
Malta	287	6	281	129
Ionian Isles	232	16	216	145
Santa Maura	6	1	5	5
Bermuda	23	4	19	100
Nova Scotia, N. Brunsw. etc.	335	30	305	149
Canada	1589	124	1455	524
Newfoundland	25	1	24	15
Naval force in Mediterranean	2598	86	2512	437
Military force in ditto . . .	2281	92	2189	629

These statistics shew an absence of any relation between the frequency of inflammatory affections of the lungs and of

phthisis. In a former part of this paper it was stated that during the previous twenty years, as compared with the last ten years, at Gibraltar, inflammatory affections were more prevalent, and at Malta they were one-third more in number, and yet, at both stations, the amount of consumption was almost identical throughout the two periods. That the fact of this total want of relation may be clearly seen, I have constructed Tables XVI and XVII.

Thus, in Bermuda, where there were only 23 cases of pneumonia, there were 100 cases of *phthisis*, and in Nova Scotia where there were nearly fifteen times as many cases of pneumonia, there were only 150 cases of *phthisis*. In Canada, with 1,589 cases of pneumonia, there were only 524 cases of *phthisis*, whereas, in the foot guards at home, with only 497 cases of pneumonia, there were 654 of *phthisis*. Again, in the naval force, 2,598 cases of pneumonia correspond with 437 cases of *phthisis*, while in the military force, 2,281 cases of pneumonia correspond with 629 of *phthisis*.

TABLE XVII.

The number of cases of "acute and chronic catarrh", with the proportion of deaths and recoveries, and the number of admissions into hospital for phthisis, among the troops, in the United Kingdom, the Mediterranean, and British America, and in the aggregates of the naval and military forces serving in the Mediterranean.

	Catarrh.	Died.	Recovered.	Phthisis.
United Kingdom :				
Dragoon guards & dragns.	7321	41	7380	386
Foot guards	4692	14	4878	654
Infantry of the line	22863	190	22673	1057
Gibraltar	3552	11	3541	176
Malta	8402	27	3375	129
Malta fencibles	62	3	59	7
Ionian Isles	2980	26	2954	145
Santa Maura	92	None.	92	5
Bermuda	1246	68	1178	100
Nova Scotia, N. Brunsw. etc.	4185	46	4139	149
Canada	11540	111	11429	524
Newfoundland	651	2	649	15
Naval force in Mediterranean	21971	27	21944	497
Military force in ditto	11314	83	11231	629

For "catarrh" we may no doubt read "bronchitis", in its various degrees; and thus, the principle that I have elsewhere laid down, that bronchitis can in no sense be regarded as a cause of tuberculosis, and that bronchitis alone can in no sense be regarded as a cause of consumption, is confirmed by these statistics. The sailor, who is half his time on deck, in periods of four hours duration, every night and day, constantly leaving his bed at twelve at night, or four in the morning, and passing from an over heated atmosphere to the open air, with exposure to all the vicissitudes of the weather, is twice as frequently attacked with catarrh or bronchitis as the soldier, who is only on guard every fourth or fifth night, and remains exposed but for two hours at a time, during which he is generally protected by his sentry box or great coat; and with this increased liability to bronchitis on the part of the sailor, and the actual occurrence of double the amount of the catarrhal affections, the sailor is much less liable to consumption than the soldier.

I have thus extracted from the original reports the statistics having a direct reference to tuberculosis, and more especially to pulmonary consumption, and placed the whole of the facts in a connected statement before the readers of the ASSOCIATION JOURNAL, believing that they are well calculated to promote the study of some very important points in the history of tuberculous diseases. I shall have occasion to refer to the tables in a future paper: in the meantime, they appear to justify the following conclusions:—

That tuberculosis is more frequent in the army, at home and abroad, than in the civil population of the United Kingdom.

That it is more frequent in the army serving at home than in the army serving either in the Mediterranean or in British America.

That it is more frequent in the army serving in the Mediterranean and Bermuda than in Canada, Nova Scotia, New Brunswick, etc., and Newfoundland.

That it is much more frequent in the army than in the navy, in the home and in the Mediterranean services.

That the season of the year has no considerable influence over the production of tuberculosis, or its local expression in the lungs, nor over its fatality, either in the United Kingdom, the Mediterranean, or in British America.

That there is no fixed relation between the amount of inflammatory diseases of the lungs and the amount of tuberculosis, or of consumption, in any of the climates. Where there is the greatest number of cases of inflammatory affections, there is often found the smallest number of cases of consumption; where there is the smallest number of inflammatory attacks, recoveries, or deaths, there is frequently the greatest number of consumptions; and in a third group, the proportionate frequency of inflammatory affections of the lungs and of consumption have a close correspondence.

3, Norfolk Crescent, Hyde Park, Oct. 1853.

CASE OF FRACTURE OF THE CRANIUM IN AN INFANT AT BIRTH.

By J. G. SWAYNE, M.D., Lecturer on Midwifery at the Bristol Medical School.

[Read at the Quarterly Meeting of the Bath and Bristol Branch of the Association, Sept. 29th, 1853.]

On Monday, June 6th, Mr. Coster, one of my pupils, was called to attend Mary M., aged 29, living in Eugene Street; the messenger desiring him to come as speedily as possible. He arrived at the house in less than a quarter of an hour, when he found the child born, and the funis broken about three inches from the umbilicus. He immediately secured the short end with a ligature, to prevent further hæmorrhage (not much, however, had occurred from the source); and then proceeded to remove the placenta, which was already detached. He was informed by a woman who was present, that the labour came on very unexpectedly, and that the patient was delivered in the upright position, the child falling on the floor. On examining the child's head, he discovered that it was much bruised, and discoloured with blood extravasated beneath the scalp and over the left parietal bone. He applied water-dressing to the injured part, and visited the mother and infant on the two following days. They both seemed to be progressing favourably, and the swelling upon the child's head had become somewhat reduced in size. For the next three days, the child took the breast fairly, as well as some food, and appeared in other respects well, until Sunday, the 12th (six days after its birth), when the mother perceived that it would no longer suck, and that the countenance was much altered.

Mr. Coster was again sent for about eight o'clock in the evening of the same day, when he found the child struggling in a severe paroxysm of convulsions. The fits recurred every five or ten minutes, and appeared to affect all the muscles of the body. The face was livid, the pulse very quick, and the pupils turned upwards, and apparently contracted. Mr. Coster directed the child to be placed in a warm bath, with cold effusion to the head, and 3j of oleum ricini to be taken immediately. The fits returned very frequently during the early part of the night, and the child seemed to be sinking fast. The pulse was very weak, and almost imperceptible. The bowels had been moved by the oil. The warm bath was repeated, with the addition of a spoonful of mustard; but the child died at half-past twelve the same night.

A post mortem examination was made on Tuesday by my request, in which I was assisted by my friend Mr. Coe, and my pupils Messrs. Coster and Granville. The child had the appearance of a healthy male infant, born at the full time.

Over the superior part of the left parietal bone, the scalp was swollen and discoloured to the extent of a half-crown piece; it had very much the appearance of one of those sanguineous tumours or cephalæmata which are occasionally formed upon the presenting part of the head, in consequence of pressure. On pressing upon it with the finger, a clot could be felt beneath the scalp, and, in the centre of this, an irregularity in the bone, which might have been caused either by a bony ridge or a fracture. The head was then opened, and the parietal bone, which was fractured, removed. On examining its inner surface, a clot of blood, rather larger than a shilling, and about a third of an inch thick in the centre, was seen between the dura mater and bone at the seat of the injury. An incision was then made into the external tumour, which laid bare a small clot between the pericranium and bone. On washing away this clot, we discovered beneath it a fissure in the parietal bone, of about an inch and a half in length. Upon that part of the surface of the brain which corresponded to the injury, the vessels of the pia mater were much congested. With this exception, there was no other morbid appearance in the brain, or in any other of the viscera which we subsequently examined. In accordance with my instructions, Mr. Coster stated, in a certificate, that the cause of death was fracture of, and effusion of blood beneath, the cranium, the result of a fall during birth.

A coroner's inquest was subsequently held upon this case, partly in consequence of our certificate, and partly because the suspicions of the neighbours were excited respecting the cause of death. The woman was unmarried, and had twice before given birth to illegitimate children. I can say very little about this inquest, as, having received no notice of it, neither of us was present; nor could we find any account of it in the Bristol papers. I believe, however, the verdict returned was in accordance with the certificate which we had given of the death.

REMARKS. This case presents some features of interest, especially in a medico-legal point of view. The time which elapsed, namely, six days, between the occurrence of the injury and the supervention of convulsions, is worthy of notice. The symptoms produced were not those of compression, properly so called, but rather such as would arise from irritation of the grey matter of the brain; and they do not appear to have been developed until the clot effused underneath the dura mater had acquired a certain degree of hardness. The convulsive attacks were in many respects analogous to those epileptic seizures which we see in the adult, as a result of pressure upon the brain from bony growths, tumours, etc.

Had it been possible to arrive at a correct diagnosis of the nature of the injury during life, the case would, I think, have justified surgical interference. The cranium might have been trephined over the fracture, and the clot removed with some prospect of success, provided the operation had been performed sufficiently early, before the symptoms of cerebral irritation had become fully developed.

In a medico-legal point of view, the case is interesting, as it shows that fracture of the child's cranium may sometimes be a result of delivery in the erect posture.

This is a subject which has been much discussed by medical jurists. Chaussier performed some experiments on the bodies of still-born children, allowing them to fall with their heads downwards on a paved floor, from a height of eighteen inches; and he found that out of fifteen cases, one or other parietal bone was fractured in twelve. On the other hand, the cases collected by Dr. Klein, of Stuttgart, show that fractures of the cranium as a result of delivery in the upright posture are exceedingly rare. Out of 183 cases, in which the women were rapidly delivered whilst standing, sitting, or kneeling, not one child died nor did any fracture of the bones or severe external injury take place. The explanation of this discrepancy between the results of cases which have actually occurred, and of analogous experiments which have been performed, may, I think, be found in the circumstance that when delivery takes place in a standing

posture, the child falls obliquely instead of directly downwards, in consequence of its following the direction of the vaginal canal which is obliquely downwards and forwards, especially near the os externum. It thus becomes expelled forwards against the clothes of the mother, and these, as well as the umbilical cord, serve to break the violence of its fall. Still, however, if we can credit the testimony of the woman and those around her, the instance I have just related proves that fracture of the cranium may occasionally result from such accidents. Although the character of these witnesses is by no means above suspicion, yet the circumstantial evidence tends to corroborate their testimony. The cord had all the appearance of having been broken and not cut. According to the account of the woman who was present at the delivery, the child was taken up from the floor, beneath a table upon which the mother was leaning at the time of its birth: and we find accordingly that the injury was exactly of that kind and in that situation where we should expect it, when a child falls upon the floor with its head downwards. There appears to have been no ground for supposing that it was inflicted by the mother or any other person present, for the purpose of destroying the child: for, had it been so, it is most improbable that the party inflicting it should not have proceeded to further violence, but have remained satisfied with the result of a blow which caused no appreciable symptoms at the time. Such a view appears to have been taken by the coroner's jury, who, by their verdict, acquitted the parties of any such intention.

Clifton, Bristol, October 1858.

SINGULAR CASE OF ALOPECIA.

By JOHN BARCLAY, M.D., Physician to the Leicester Infirmary.

[Read at the Meeting of the Midland Branch of the Association, at Leicester, on Sept. 1st, 1858.]

MR. A. B. applied to me in February last on account of complete baldness. He is twenty-four years of age, a printer, of florid complexion, sanguine temperament, steady habits, and married.

He had been working hard in a close and confined room seven months previously, when he noticed the hair begin to fall from the scalp. This was soon denuded, and then his beard and whiskers followed. The hair on the pubes and in the axillæ, on the arms and legs, next disappeared, and lastly, the eyebrows and eyelashes, so that when I saw him, he was perfectly hairless from head to foot.

His general health was considerably affected; his appetite was good; but the digestion impaired; and he complained of a sensation of languor and general debility. The excreta were normal. I ordered him a preparation of steel, and friction of the scalp, with a stimulating liniment. The form in which I prescribed the latter was two drachms of tinctura lyttæ to half a pint of rosemary water, which I have usually found a very successful remedy.

In three or four weeks, he found the smarting cease to be produced by this strength of the lotion, and there was no improvement in the state of the skin. I directed him to increase the proportion of the tinctura lyttæ at his own discretion.

By the end of the second month of treatment, he had gradually come to use pure tinctura lyttæ for friction to the head, the skin of which was totally insensible to its effects, while the fingers smarted considerably while applying it.

He has continued the internal remedies with slight intermissions up to the present time, with very marked benefit to his general health, which is now quite reestablished; but there is not the slightest appearance of a return of the hair on any part of the body. When examined with a lens, the bulb of the hair seems gone, but the root is still there through which the hair penetrated the cuticle. There is a slight down upon the ears, which has just appeared; but with this exception, he remains hairless.

I have recommended sea air and bathing, but this is difficult of attainment to one dependent on his own industry in the Midland Counties.

It is the only case of complete alopecia I have ever met with in the course of my practice; and I am not aware of any recorded instances.

Leicester, September 1st, 1853.

PERISCOPIC REVIEW.

MICROSCOPICAL DISCOVERY.

MUSCULAR TISSUE OF THE HUMAN SKIN.

In the fourth number of the *Journal of Microscopical Science*, Mr. JOSEPH LISTER gives interesting confirmation of Kölliker's account of the muscles of the true skin.

Portions of the skin having been partially dried, and then cut into thin slices, exhibit, when again moistened, delicate bands of unstriated muscle, rising in the surface of the dermis, close to the epithelium, and thence descending obliquely, to be inserted into the hair-follicles. "The muscles are seen to arise in all

cases from the most superficial part of the corium, and to pass down obliquely to their insertions into the hair follicles immediately below the sebaceous glands." In sections made as above described, it is at once remarked, that all the muscles (a 1, a 2, a 3, a 4, etc., of the annexed figure) are on the same side of the respective hair follicles, viz., on that side to which the hair slopes. This arrangement of the muscles is exactly that which is best adapted for erecting as well as protruding the hairs, which must be drawn by their contraction nearer to the perpendicular. That this erection as well as protrusion of the hairs does occur, our author has satisfied himself by artificially exciting the state of "cutis anserina" on his own arm and leg. Tickling a neighbouring part will often induce horripilation; and if the eye is kept on an individual hair at this time, it is seen to rise quickly as the skin becomes rough, and to fall again as the horripilation subsides. Each hair-follicle of the scalp possesses but one muscle. Mr. Lister has not been able to confirm Henle's statement, that muscular fibres exist in parts of the skin destitute of hair, such as the palm and the sole.

From these researches, it is obvious that there exists an intra-dermal muscular tissue, the function of which is to move the hair follicles, and perhaps, by some degree of pressure, to stimulate the glands which lie close to the muscles to increased secretion.

GLANDS IN CONNEXION WITH THE EYE AND NOSE.

Dr. SAPPEY has published, in the recent numbers of the *Gazette Médicale* (Nos. 33, 34, 35), some researches on the glandular secreting apparatus of the eye and nostrils.

He describes the orbital and palpebral portions of the *lachrymal gland* as usual, and states that the ducts passing from the former, to the number of three, four, or five, pass through the inferior division of the gland, on their way to the conjunctiva, and receive in this course the secretion of some of the lobules of that part of the organ; while the greater part of these lobules pour their secretion into two or three separate ducts, which pierce the conjunctiva in a line with those before mentioned. The acini of the lachrymal gland Dr. Sappey has succeeded in injecting with mercury.

The *subconjunctival glands* are from ten to twenty-five in number, conglobate; and each pours its secretion by the duct upon the surface of the membrane, where it is reflected from the lid upon the eyeball at its upper nasal aspect. The *ciliary sebaceous glands* are two to each eyelash, and quite resemble the sebaceous glands of the hairs in other parts of the body: it is these, and not the Meibomian glands, which pour out the secretion so usually noticed in ophthalmia tarsi.

The mucous secretion of the nose is poured out, according to Dr. Sappey, not from follicles, but from glands, not unlike in general arrangement to the Meibomian glands of the eyelids. They consist of grape-like bunches of acini, arranged along the excretory duct, into which they pour their secretion by short subsidiary branches. The main ducts run vertically through the mucous membrane, and open by circular orifices on its surface. In some parts of the nasal mucous membrane, as on the anterior part of the outer wall of the nostrils, they are very numerous; in others, more widely scattered. Our author has not succeeded in finding these glands in the thin membrane of the frontal and maxillary sinuses.

BLOOD-VESSELS OF THE LUNGS.

Dr. JAMES NEWTON BEALE has submitted to the Royal Society (*Phil. Mag.*, September) the results of a series of careful injections of the pulmonary and bronchial vessels, which, he finds, have no communication whatever with one another; and

the most novel result of his investigations is, that the so called bronchial artery does not supply the bronchi at all.

The pulmonary artery may be thoroughly injected without the fluid passing in the least degree into the "bronchial" vessels, and vice versa.

i. The pulmonary artery makes no anastomosis whatever with any other artery, nor do its own branches anastomose with one another; its branches are distributed directly to the air-cells, and none go to any of the other tissues of the lungs, except some few which perforate the subpleural cellular tissue, and are distributed to the pleura; some of these also cross the posterior mediastinum, beneath the pleura, and reach the thoracic pleura.

ii. The bronchial arteries end in veins, which ramify in the subpleural cellular tissue; the cellular tissue of the lung being the part supplied by these (so called) bronchial vessels. The greater part of these bronchial veins pass into the posterior mediastinum, and empty themselves into the oesophageal and other veins.

iii. The bronchial mucous membrane is very freely supplied with a very close plexus of vessels, of a peculiar and very characteristic description, which is found to ramify in every part of the bronchial membranes, even as high as the trachea. The whole of this plexus is a continuation of the vascular plexus of the air-cells, and therefore derived from the *pulmonary artery*, but only thus indirectly, as no branch of that vessel goes directly to the mucous membrane.

iv. The pulmonary veins are formed by the junction of two distinct sets of radicles: one set derived from that part of the air-cells most distant from the minute terminal bronchus entering each lobule, and which radicles form small trunks visible on the surface of the lung between the lobules. The other set is derived from the bases of the pulmonary lobule, and go to supply the bronchial mucous membrane before entering the pulmonary vein.

v. The coats of the lymphatic vessels of the lung are supplied by blood-vessels derived from the air-cells, and which terminate in the pulmonary veins; and the distribution of blood-vessels on the coats of the lymphatics bears a strong resemblance to that of the capillaries on the bronchial mucous membrane.

PARASITES OF THE HUMAN SKIN.

Dr. CABELL, of Richmond, Va., gives, in the *Virginia Medical and Surgical Journal* for April, a somewhat novel account of these parasites of the follicle and hair sac, which, however ugly, seem innocent creatures, in comparison, at all events, of *Acarus Scabiei*. We copy his description and figures.

"I have seen three distinct kinds of these parasites. The first, marked No. 1, is called *entozoon folliculorum*; it has a head, eight short legs, and a long cylindrical body. The head is composed of a proboscis placed between two palpi; the proboscis as well as the head and limbs can be protruded and retracted. The thorax is divided into four obscure rings, one corresponding with each pair of legs, and has a distinct line of demarcation separating it from the abdomen. This animalcule possesses great tenacity of life, and lives many hours in oil, moving and retracting its limbs and head. The length of the parasite is .26 of a millimetre; the millimetre being about half a line. The second in order is much longer; has only six legs, and a very long and tapering abdomen. The head is similar to No. 1, but its thorax melts insensibly into its abdomen; both engravings represent the parasites each with one leg retracted completely, having the appearance of a mere ring. The length of No. 2 is .35 of a millimetre. The imperfect or embryonic entozoons, No. 3, are only .03 of a millimetre, and have been seen by me only in the sac, with the short eight legged parasite. The last one to be mentioned differs from the others both in shape and colour. I have found it once only. Whether the hair follicle is its proper habitation, or whether it found its way there accidentally, I am unable to say; but it is certainly capable of existing there as well as the parasites first described; for it is equally minute, being invisible to the unassisted eye. Its colour is orange red, and its form so much like the acari, that I have applied the name *acarus folliculorum* to it, and have always spoken of the other parasites simply as entozoons. Its length is .26 of a millimetre; the head is very long, and mitre shaped, and contains between its two divisions a lancet shaped organ, resembling a tongue. The thorax is very short, and has articulated to it the two anterior pairs of legs, which have many articulations, are shorter than the posterior, and terminated by two claws. The abdomen is rounded, covered with hairs, which are irregularly and sparsely scattered over the body and limbs, more abundant at the articulations. The posterior pairs of legs are much longer than the anterior, and terminate not in claws, but in many long and stiff hairs. The body is filled up with a granular, oleaginous looking substance; and since the preparation in Canada balsam has grown transparent by keeping, six or eight globular bodies, all of the same size, and looking like eggs, have been observed in the interior of the abdomen."

No. 1.

No. 2.

No. 3.

¶ The Nos. 1 and 2 of the above description seem to correspond with the animal well known from Mr. Wilson's description. We entertain great doubts whether they actually are distinct species; different sex would account for all the difference between them, save in the number of legs; and perhaps, if they are militant creatures, the chances of war may supply a reason for this. As to the "*Acarus*", since but one specimen has hitherto been seen, we prefer suspending our judgment on its actual citizenship of the American body.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

SATURDAY, OCTOBER 8TH, 1853.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.

INTRODUCTORY REMARKS.

The PRESIDENT said that, as he was about to read a paper, he would not occupy much time with preliminary remarks. There were, however, one or two topics to which he would briefly allude.

Cholera had reappeared with virulence. He would suggest that it might be a subject to be taken into special consideration by the Society, in order to endeavour to obtain clearer notions of the pathology and treatment of the disease.

A physiological section had been established: and he trusted that the Fellows of the Society would show their interest in it by attending its meetings.

There was also a point of melancholy interest to which he must allude—the death of Mr. W. F. Barlow, who had been appointed orator for the ensuing anniversary meeting. He (the President) had no personal knowledge of Mr. Barlow, beyond having met him at the Society and elsewhere; but from perusal of his writings, and from all that he had heard concerning him, he would certainly say that, in the death of Mr. Barlow, the Medical Society and the profession at large have sustained a great loss.

ABNORMAL PLACENTA. BY EDWARDS CRISP, M.D.

Dr. CRISP exhibited a placenta, and gave the following history of the case. Mrs. D. applied on August 24th to a surgeon in the Kennington Road to be attended in her confinement. She was then six months advanced in pregnancy: she was larger than usual, and had anasarca. Diuretics were given, and she went on favourably till the 31st. On that day, symptoms of labour appeared; and she lost much blood by uterine hæmorrhage. On seeing her, the surgeon, finding that the hæmorrhage had abated, determined not to interfere at present. In some hours, the pains increased; the membranes were ruptured, and a fœtus was expelled, which had apparently been dead some days. Two or three coagula were expelled with the fœtus; but there was no further hæmorrhage. In a quarter of an hour, the placenta of the child was thrown off. The uterus still feeling large, a second child was thought to be present: but when the mass which Dr. Crisp exhibited had been expelled, it returned to its usual size after delivery.

The weight of the placental mass exhibited was nine ounces. Its uterine surface presented the usual appearance; on the foetal surface there was no trace of an umbilical cord, but only an aperture from which the vessels seemed to diverge. The tufts resembled those of a normal placenta, but were very distinct: hence it presented the appearance of a placenta which had been long subjected to the action of water. There was no fatty degeneration.

The patient had miscarried in December 1852; the placenta was then expelled. She had felt no pain in the side until a fortnight before being seen, when she became anasarctous. Dr. Crisp suggested several questions, as arising from this case. How long had the placenta been present in the uterus? Had there been twins, of which one had been expelled at an early period? Could the placenta be nourished by the uterine vessels alone?

ON SOME UNRECOGNISED FORMS OF MENTAL DISORDERS. BY FORBES WINSLOW, M.D., D.C.L.

Dr. WINSLOW directed attention to some complicated, varied, and often obscure affections of the nervous system, disordering the mind. These morbid states might be viewed as pseudo, anomalous, and eccentric deviations from certain predetermined, cerebral, and psychological conditions. He wished to avoid the discussion of the question "what constitutes insanity?" He would restrict the term to deviations from mental health, accompanied by positive aberrations of the ideas, conjoined with lesions of volition, clearly justifying the exercise of moral restraint; and to those derangements of the intellect which authorise us in bringing these subjects under the protective influence of the law. The author was anxious to confine his attention to those cases where the mind might be said to be pathologically disordered, but not legally insane; and to draw notice to a large class of cases of disordered intellect, arising upon the surface of society, which had not hitherto been sufficiently recognised as the effect of certain social conditions, bringing those so affected within the medical treatment.

The disorders to which he referred were confined principally to the passions, affections, propensities, and moral sense. The attack often assumed the character of an exaggeration of some single passion, appetite, or emotion. This morbid cerebral state might exist without arresting medical attention, or demanding legal interference. These affections were generally insidious, of slow growth, and almost imperceptibly originating important organic alterations in the manifestations of the passions and affections. As this mental disorder frequently exhibits itself in a perversion of the feelings, alienation of the affections and erratic conduct, it engenders much concealed misery in domestic life. The patient may commit acts of cruelty and brutality towards those who have the strongest claims upon his affections. The naturally gentle, truthful, retiring, and self-denying, may become quarrelsome, cunning, and selfish; the diffident, bold; the modest, obscene; piety may degenerate into hypocrisy, or be exalted into fanaticism. Persons so affected manifest the characteristics of intemperance, both in thought and action, they are wayward and eccentric; their extraordinary conduct often giving rise to the suspicion, that they are either drunk or mad. Occasionally the disorder exhibits itself in a want of veracity amounting to disease.

In these anomalous pathological conditions of the mind, the reasoning and reflective faculties remain intact; hence the actual state of those disordered is not suspected, even by their most intimate associates, until the affection becomes apparent by the commission of some overt act of insanity. A person with a mind under the influence of positive disease has been known for a period to exercise great power of self-control. He may perform common duties in life without exhibiting very conclusive evidence to others of his actual morbid condition. He may be an unrecognised monomaniac, acting under the terrible and despotical influence of one predominant morbid idea, bringing ruin and desolation upon his once happy home; he may recklessly squander a fortune, which he has only accumulated after years of anxious toil; he may become brutal, vicious, criminal, a drunkard, a suicide, as the result of an undoubtedly morbid state of the mind; and yet pass through life as a sane, rational, and healthy man. In actual practice, all the varied shades of such unrecognised mental alienation are met with. The patients exhibit violent antipathies, harbour unjust suspicions, affect singularity of dress, gait, and conversation, are easily excited, are subject to violent and ungovernable paroxysms of passion from the most trivial causes, are lost to all sensibility and delicacy of sentiment, refinement of manner and conversation, are often obstinately riveted to the most absurd dogmas, and are prone to controversy. The disorder may manifest itself in morbid imitation, in inordinate mad ambition, in desire of praise or of notoriety, in a depressed, exalted, or vitiated state of the sexual appetite, or in morbid views of religion; and it is often associated with profound anaesthesia of the moral sense.

These affections are symptomatic in many cases of unobserved cerebral disorder, either originating in the encephalon, or produced by sympathy with morbid processes existing in other tissues in close organic relation with the great nervous centre. These conditions occasionally succeed febrile attacks involving the brain and nervous system, and often follow injuries of the head, inflicted either in early or in advanced life. They are also seen in association with genius; and, as the biographies of Cowper, Burns, Byron, Johnson, and Pope establish, the best and most highly gifted conditions of the mind do not escape.

Dr. Winslow then cited the particulars of several cases illustrative of each form of this class of unobserved mental alienation. He then referred to two other forms of oinomania, or insanity exhibiting itself in uncontrollable habits of intemperance, and to cases of neglected suicidal insanity. He then directed attention to the amount of untreated mental depression, associated with an irresistible suicidal propensity, which had prevailed within the last twelve or eighteen months. In many cases it had appeared from the evidence at the coroner's court, that the mental disorder had existed for weeks, and sometimes for months, without giving rise to suspicion of the presence of a dangerous degree of cerebral mischief. There are few morbid mental conditions so fatal as these apparently trifling, evanescent, and occasionally fugitive attacks of mental depression. This state of the brain is almost invariably associated with the suicidal impulse. Many persons, apparently rational, have committed suicide under the overpowering influence of some latent and concealed delusion. A patient, in his autobiography, described himself as having for three months had the idea of suicide constantly in his mind. His wife, friends, his children, observed his despondency; but they knew nothing of the "worm that gnawed within". Is this not a type of case more generally pre-

valent than we imagine? May not this man, with a mind driven to despair by a terrible concealed hallucination, be urged to suicide as his only escape from misery:—

"He hears a voice we cannot hear,
Which says he must not stay;
He sees a hand we cannot see,
That beckons him away."

The author, after making some observations on oinomania, and pointing out the necessity of recognising this form of cerebral disease as one amenable to treatment, adverted to a phase of mental alienation occupying a kind of neutral ground between positive lunacy and the stage of incubation, accompanied with intense consciousness of the presence of a morbid condition of mind. The patient knows that he is not as he should be, and prays earnestly for relief from his acute sufferings. Up to a certain point the power of self-control is retained, and the case affords to superficial observers no positive symptoms of mental alienation. In this intermediate state, patients often ask, "Am I insane?" He then referred at some length to the characters of Hamlet and Lady Constance, and cited passages from Shakespeare illustrative of this strange phase of morbid mind. An excellent illustration is afforded in the passionate exclamation of the Lady Constance, in reply to the legate's assertion of her madness:—

"Pand. Lady, you utter madness, and not sorrow.

Const. Thou art not holy to belie me so;

I am not mad: this hair I tear, is mine;

My name is Constance: I was Geoffrey's wife;

Young Arthur is my son, and he is lost;

I am not mad—I would to heaven, I were!

For then, 'tis like I should forget myself:

O, if I could, what grief should I forget!

Preach some philosophy to make me mad,

And thou shalt be canonized, cardinal;

For, not being mad, but sensible of grief,

My reasonable part produces reason

How I may be delivered of these woes,

And teaches me to kill or hang myself;

If I were mad, I should forget my son;

Or madly think a babe of clouts were he:

I am not mad; too well, too well I feel

The different plague of each calamity."—*King John*, act III, s. 4.

He observed that he might be asked, How can we accurately diagnose between such morbid conditions, and those natural states of the passions, emotions, and appetites which, though fraught with mischief, must be viewed as healthy manifestations? It is often the sudden and prolonged departure from natural habits, feelings, and passions, that justify a suspicion of the existence of mental alienation. This disorder of the mind is occasionally exhibited in simple exaggeration of one predominant passion or train of thought; and in these, as in other cases, the only safe standard is the ordinary character of the patient. A man may be brutal, subject to violent passions, licentious improvidence, and yet be sane; nevertheless, in many cases, all these symptoms constitute conclusive evidence of the existence of serious mental disorder. A naturally irritable man may be excited by circumstances calculated to engender a state of emotion; but the passion allied to insanity is often fanned into a flame by the most trifling causes. Healthy passion generally subsides after the removal of the exciting cause; but such is not the case with morbid emotions. Apart from the susceptibility to passionate excitement and the presence of great irritability of temper, the physician will generally discover other mental and physical variations from the natural and healthy conditions of the mind and body, which will assist him in arriving at a safe diagnosis. This morbid condition, whether exhibited in ungovernable passion, in alienation of affection, in perverted appetites, in irritability of conduct, or in loss of all sense of right and wrong, is generally associated with restless days and sleepless nights, as well as with impairment of the general health. Every case, however, must be viewed in relation to its individual characteristics, and to itself as a standard, and not in reference to any *a priori* theory, or predetermined test.

An interesting discussion ensued, in which Drs. Copland, Webster, Sibson, Cormack, and others, took part; but which, from other demands upon our space, we are unable to report.

PHYSIOLOGICAL SECTION.

MONDAY, OCTOBER 10TH, 1853.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.

VALVES IN THE SPLENIC VEINS. BY EDWARDS CRISP, M.D.

Dr. CRISP exhibited several preparations and drawings of the splenic veins of various ruminant and rodent animals, with the object of shewing the existence of valves—a fact which seems to have hitherto escaped the attention of anatomists. In the horse, they are generally numerous; they vary, however, in number

very much in different individuals of the same species of animals. He had not found the valves in the mesenteric or other abdominal veins. It was only in certain classes of animals that they existed; in man and the quadrumana he had searched for them in vain.

Mr. RICHARDSON thought that Dr. Crisp had a distinct claim to the discovery of the valves in the splenic veins. There seemed no reason why the splenic veins should be valveless; but probably anatomists had concluded that it was so, from the absence of valves in the vena cava, and other abdominal veins. There are anatomical reasons why the vena cava should not have valves; for instance, in the pressure exerted by a gravid uterus they would have a most injurious effect.

MODE OF ACTION OF MORBID POISONS, AND OF THE SYPHILITIC POISON IN PARTICULAR. BY HENRY LEE, ESQ.

Mr. LEE divided poisons into those which begin to produce their effects immediately on their application, and those in which a certain time must elapse. The first class are absorbed in three ways: 1. Directly into the blood; 2. By the lacteals; 3. By the lymphatics; and to these we may add a fourth method, viz.; by local effect on the nerves. To the second class, those poisons which require a certain time to elapse before producing their effects, belongs the syphilitic poison. Mr. Lee entered on a critical examination of the doctrine of Hunter, that venereal infection takes place through the lymphatics; and contrasted his experiments on absorption with those of Tiedemann and Gmelin, Magendie, Segalas, etc. The latter observers had shown conclusively that veins absorb. Primary syphilitic sores were described as being either indurated, ulcerated, suppurative, or gangrenous; and Mr. Lee enunciated the law that an indurated primary sore is pretty certain to be followed by secondary symptoms, while a suppurative or ulcerative sore is almost always accompanied by a bubo, but is not followed by secondary symptoms. Constitutional symptoms seem to occur in an inverse ratio to affection of the lymphatics. Where there is suppuration or ulceration, the nidus of the poison is destroyed.

Especial allusion was made by Mr. Lee to the non-occurrence of secondary symptoms after inoculation, in the experiments made on syphilisation. This he explained by the fact that, in persons already affected, a fresh sore is almost always suppurative or ulcerative; and, in inoculation, a number of small sores are produced, having very much the same effect as a larger suppurative bubo.

Mr. Lee believed that the syphilitic virus loses its specific influence by passage through lymphatic glands; and he compared this with the experiments of the Abbé Fontana on the poison of the viper when taken into the stomach, and with those of Pelouze and Bernard on the Woorara poison.

Beyond the point of absorption, some changes are going on, perhaps, in the molecular structure. If we remove a chancre with the knife, in a few days the cut surface will assume a specific character. Hence Mr. Lee thought the blood in the neighbourhood of the sore infected rather than the lymphatics.

Dr. LANKESTER congratulated the Society on the opening of its physiological section. It might appear to some that Mr. Lee's paper was more pathological than physiological; he believed, however, that it was a very fit paper for the section, because physiology and pathology must go hand in hand in order to produce a good result. It is the general opinion that poison-diseases arise from some condition of the blood, but of the nature of which the microscope and chemistry have failed to inform us. He would ask Mr. Lee whether he had made microscopic examinations of the blood or pus in syphilis; and whether he thought that the whole blood was infected, or only for a certain distance round the sore?

Dr. SNOW believed that it is in the extra-vascular liquor sanguinis that the first action of such poisons as the syphilitic is first manifested. He referred to the occurrence of an indurated bubo in the groin, between the appearance of the primary sore and of secondary symptoms.

Mr. DE MÉNÉZ criticised Mr. Lee for having laid down a very attractive theory, without supporting it by sufficient facts.

Mr. RICHARDSON was surprised that the author had recognised the direct action of poisons on the nerves.

After some further discussion on the action of poisons between Drs. Crisp and Cogswell, Mr. Richardson, and Drs. Camps and James Bird, Mr. Lee replied, and the meeting adjourned.

EDITOR'S LETTER BOX.

MEDICAL ETHICS AND ASSOCIATION REFORM.

LETTER TO THE EDITOR.

SIR,—You will much oblige me by printing in the Journal the accompanying advertisements issued by members of the Association. I do not ask you to say whether they are professional or unprofessional; but I think you cannot object to give them a place for the general edification of our members, the majority of whom have no access to the newspapers in which they originally appeared.

I am one of those who long to see accomplished what you have often hinted at—the formation of a code of ethical laws, and the formation of a representative Council to enforce them. The General Council is, from its very nature, inoperative.

The first advertisement is from Dr. FAIRCLOTH, of Northampton, and runs thus:—

"Dr. FAIRCLOTH, M.D., Marischal College and University, Aberdeen, Fellow of the College of Surgeons of England, Senior Medical Officer of the Royal Dispensary, Northampton, and formerly a resident House Pupil in the General Infirmary at Northampton, etc., respectfully announces that he has commenced practising in the Higher Branches of his Profession."

—*Northampton Mercury*.

The next advertisement is by Mr. H. L. SMITH, of Southam, and is as follows:—

"Mr. SMITH, Member of the Royal College of Surgeons of London, Oculist and Aurist to the Infirmary of Southam, Warwickshire, for curing Diseases of the Eye and Ear, will attend at the George Hotel, Northampton, on the FIRST TUESDAY in each month.

"Subscribers to the Infirmary, in the vicinity of Northampton, sending patients, with recommendations, to consult Mr. Smith at the George Hotel, are requested to desire them to attend exactly at twelve o'clock."—*Northampton Herald*.

Is the Medico-Ethical Committee appointed at Swansea in operation? If so, allow me to suggest to its Secretary the advantages which would result from its proceedings being reported from time to time in the Journal. Members of the Association might often have valuable suggestions to make to the Committee, either privately, or through the Journal.

The numbers and the status of our members entitle our Association to take a higher ethical position than it at present possesses; and, had I not the belief that there is an awakening in our ranks to the importance of an ethical and general reform of our constitution, I would not subscribe myself, as I now do with sincerity,

A HOPEFUL MEMBER.

October 10th, 1859.

MEDICAL EDUCATION.

LICENSING BODIES IN SCOTLAND.

The following are the Licensing bodies in Scotland:—

EDINBURGH.—UNIVERSITY.

—ROYAL COLLEGE OF PHYSICIANS.

—ROYAL COLLEGE OF SURGEONS.

GLASGOW.—UNIVERSITY.

—FACULTY OF PHYSICIANS AND SURGEONS.

ABERDEEN.—UNIVERSITY AND KING'S COLLEGE.

ST. ANDREW'S.—UNIVERSITY.

UNIVERSITY OF EDINBURGH.

PRINCIPAL: John Lee, D.D. SECRETARY: Blair Wilson, Esq. DEGREE OF M.D. The candidate must have studied *four* years, during at least six months of each, in the University of Edinburgh, or in some other university where the degree of M.D. is given; unless, in addition to three *and* *medicis* in an university, he has attended, during six winter months, the medical and surgical practice of a general hospital, with at least eighty patients, and during the same period a course of *practical* anatomy.

He must give evidence—That he has studied in *an* university, anatomy, chemistry, *materia medica* and *pharmacology*, institutes of medicine, surgery, practice of medicine, the diseases of women and children, general *pathology* and anatomy (unless attended in the year of *extra* *medicis* allowed), during courses of six months: *clinical* *medicine*.

a course of six months, or two courses of three months each : and clinical surgery, medical jurisprudence, botany, and natural history, including zoology, during courses of three months. That besides clinical medicine, he has attended, for six months of another year, the medical or surgical practice of a general hospital, accommodating eighty patients. That he has attended, for at least six months, by apprenticeship or otherwise, the art of compounding and dispensing drugs. That he has attended, for at least six months, by apprenticeship or otherwise, the out-practice of an hospital, or the practice of a dispensary, or that of a physician, surgeon, or member of the London or Dublin Society of Apothecaries. That he has studied, for one year previous to his graduation, in the University of Edinburgh.

Every candidate for the degree of medicine must deliver before the 31st of March of the year in which he proposes to graduate, to the dean of the faculty of medicine,—A declaration, in his own handwriting, that he is twenty-one years of age, or will be so before the day of graduation; and that he will not be then under articles of apprenticeship to any surgeon or other master. A statement of his studies in literature, philosophy, and medicine, accompanied with certificates. A medical dissertation, composed by himself, in Latin or English.

Before a candidate be examined in medicine, the medical faculty shall ascertain, by examination, that he possesses a competent knowledge of Latin. They shall then examine him, *visd voce*, or in writing—1. On anatomy, chemistry, botany, institutes of medicine, and natural history, bearing chiefly on zoology; and 2. On materia medica, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence. Students may be admitted to an examination on the first division at the end of the third year of their studies.

If the candidate have satisfied the medical faculty, he will be summoned, on the 31st of July, to defend his thesis; and if the senate think fit, he shall be admitted on the first lawful day of August, to the degree of Doctor.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

No one is admissible as a fellow who has not obtained the degree of M.D. All petitions for the fellowship are determined by ballot. Graduates of foreign universities must submit to an examination before the examiners of the College, which shall consist—1. Of a dissertation in English, on some subject in the practice of physic selected by the examiners. 2. Of a *visd voce* examination in English, chiefly on symptomatology, pathology, and therapeutics of diseases; but in part, also, on anatomy, chemistry, botany, and physiology. 3. The examiners may institute such examination as they may consider advisable for satisfying themselves that the candidate has received a competent education.

The mode of election of a non-resident is the same as that of a resident fellow.

FEES. For a resident fellowship, £130; for a non-resident, £80; both inclusive of stamp duty. Fee paid by a resident licentiate, £100; by a non-resident £55; exclusive of any tax payable to government. Every resident fellow pays an annual subscription of £1 : 1 to defray the College expenses.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.

Every candidate for a diploma must have followed the course of study, to be specified afterwards, in an university, or at the seat of an established school of medicine; the lectures delivered at a provincial school will be held as qualifying for one year's course of study, unless specially recognised for more.

COURSE OF STUDY. 1. Preliminary Instruction. Every candidate must have received instruction in the elements of mathematics, mechanical philosophy, and the Latin language.

2. Professional Instruction. The candidate must have been engaged during a period of not less than twenty-seven months, including three winter sessions, in attending—

Anatomy, two courses of six months each. Practical Anatomy, twelve months. Chemistry, Materia Medica, and Pharmacy, Institutes of Medicine or Physiology, Practice of Medicine, and Clinical Medicine, of each one course of six months, or of the last, two courses of three months each, during the period of hospital attendance. Principles and Practice of Surgery, two courses, six months each; or Principles and Practice of Surgery and Military Surgery, one course, six months each. Clinical Surgery, one course, six months; or two courses, three months each; during the period of his attendance at the hospital where they are delivered. Midwifery and Diseases of Women and Children, one course, three months. Medical Jurisprudence, one course, three months. Practical Chemistry, one course, three months, the number of pupils in each class being limited to twenty-five; or Analytical Chemistry, three months. Also a

course of instruction in Practical Pharmacy, at the laboratory of a surgeon or apothecary; or of a chemist and druggist recognised by the College; or of a public hospital or dispensary: and he must produce evidence that he has been engaged in compounding and dispensing medicines for six months. Those who produce certificates of having been for two years pupils or apprentices of regularly licensed practitioners, keeping laboratories for dispensing medicines, shall be held qualified in this branch.

The six-months' courses delivered in Edinburgh must consist of not fewer than a hundred and ten lectures, with the exception of clinical medicine, clinical surgery, and military surgery. The three-months' courses must consist of not fewer than sixty lectures. Two London courses of three months each will be taken as equivalent to one six-months' course.

The candidate must also have attended, for twenty-one months, a public general hospital containing on an average eighty patients.

Every candidate, on applying to the president, will be required 1. To produce evidence of his having attained the age of twenty-one years. 2. To present a tabular statement exhibiting the amount of his professional education. Unsuccessful candidates will be remitted to their studies for a period not, in any case, less than three months. Every candidate will be required to translate into English some portion of a Latin author.

FEE. For a diploma, £10; including all fees.

UNIVERSITY OF GLASGOW.

PRINCIPAL: Duncan Macfarlan, D.D. **CLERK OF SENATE:** Allen Thomson, M.D.

DEGREES IN MEDICINE. 1. Every candidate must lodge with the Clerk of Senate a certificate of moral character, with evidence that he has attained the age of twenty-one years.

2. He must have attended, for four Winter Sessions of six months each, an university in which medical degrees are conferred, and medicine is regularly taught. He must spend one at least of the four years at the University of Glasgow; and in each year he must have attended at least two courses of six months' duration. If he shall spend only one year or session at the University of Glasgow, he must attend not less than three courses of lectures delivered there, two of them at least being of six months' duration. If of less extent, two courses shall be held equivalent to one of six months.

3. He must produce certificates of attendance on the following courses of instruction, each of six months, with the exceptions mentioned below:—Anatomy; Chemistry; Institutes of Medicine; Botany, three months; Materia Medica and Pharmacy; Surgery; Practice of Medicine; Midwifery; Forensic Medicine, three months; Anatomical Dissections; Practical Chemistry, three months; General Hospital, two years, of not less than nine months each, or eighteen months. The hospital must contain eighty beds; clinical instruction must be given; and the student must spend at least half of the period in the physicians' wards.

4. Each candidate must lodge with the Clerk of Senate the above certificates, and a schedule of his course of study filled up, with an essay composed by himself on some medical subject of his own selection, on or before the 1st of March or the 10th of June.

5. No student shall be entered in any medical class later than the 1st of December (excepting those which do not meet till a later period) without the permission of the Senate; and every candidate for graduation shall be required to have his name enrolled in the University, on or before that day.

6. The examination shall be conducted partly in writing. Previous to the professional examination, the candidate shall give evidence that he possesses a competent knowledge of the Latin language; this examination in the Latin language may, at the option of the candidate, be in any year previous to the professional examination.

The examination shall be divided into two parts; the first comprehending Anatomy, Chemistry, Institutes of Medicine, and Botany; the second, the Principles and Practice of Medicine and Surgery, Materia Medica and Pharmacy, Midwifery, and Forensic Medicine. The candidate may undergo the first examination at the end of his second Winter Session, or at any of the following examination terms, provided he shall have attended the necessary lectures.

DEGREES IN SURGERY. The regulations are analogous to those for degrees in medicine.

The days appointed for conferring degrees in medicine and surgery are the last Wednesday of April, and the first Wednesday of August.

Fees for the degree of M.D., £15 : 8; government duty on

stamp for ditto, £10; fee for the degree of Chirurgie Magister, £10:10.

FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.

PRELIMINARY INSTRUCTION. Every candidate for the diploma must, either previously to or during his medical education, have received instruction in the elements of mathematics, in mechanical philosophy (by attendance on a course of not fewer than sixty lectures), and in the Latin language.

PROFESSIONAL INSTRUCTION. The candidate must have attended the following distinct courses of lectures during not less than twenty-seven months, in which must have been included three winter sessions of six months' duration each:—

Anatomy, practical anatomy, and surgery, two courses of six months; or surgery and military surgery, one course of six months; chemistry, one course of six months; practical chemistry, one course of three months; institutes of medicine, practice of medicine, materia medica, and midwifery and diseases of women and children, one course of six months each; clinical medicine and clinical surgery, two courses of three months each; medical jurisprudence and police, one course of six months; botany, one course of three months; general hospital, with at least eighty beds, twenty-one months; practical pharmacy, at the laboratory of a surgeon or apothecary, or of a public hospital or dispensary, or at that of a chemist or druggist recognised by the Faculty, six months. The Faculty recommend lectures on the eye, and Hospital for Eye Diseases. A three months' course of lectures on the eye, with six months' attendance on an Eye Hospital, will be considered equivalent to three months of a General Hospital. Lying-in Hospital. Hospital for Syphilitic Diseases. Pathological anatomy. Natural history and comparative anatomy. Greek, French, German, and Italian.

Each candidate shall be examined, partly orally, and partly by written question and answer. He shall translate Latin, write prescriptions, and be examined in preparations. The Committee of Examiners being satisfied, the candidate shall be entitled to his diploma, on subscribing the declaration authorised by law in place of extra-judicial oaths.

The unsuccessful candidates shall be remitted for not less than three months after a first rejection, and six months after a second, and their names shall be concealed. The whole of the deposited fee shall be returned on a first rejection; but on every future similar occasion, whether the examination may have been before the Faculty, or any other licensing board, or when the candidate, prior to application for a surgical license, may have been five years in practice, two guineas shall be retained.

Examination in Latin, on the second and following Saturdays in December, annually. Students who have taken a degree in Arts, from a University of Great Britain or Ireland, will be exempted from these examinations.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

MEDICINE. Candidates for the degree of M.D. must be of the age of twenty-one years; they must produce satisfactory certificates of moral character, and of having studied classics and mathematics at an university, or at an academy of acknowledged reputation. All candidates, with the exceptions mentioned below, must have studied medicine for four years—one of which must be passed at King's College, Aberdeen—and must produce evidence of having attended the following courses:—Six months' courses: Anatomy, two courses; chemistry, one course; materia medica, one course; surgery, one course; institutes of medicine and physiology, one course; practice of medicine, one course; midwifery, one course. Three months' courses: Dissections, two courses; practical chemistry, one course; medical jurisprudence, one course; clinical surgery, one course; botany, one course; clinical medicine, two courses. Attendance on at least two courses is requisite to constitute an *annus medicus*. Certificates of attendance on a six-months' course of chemistry, previous to the commencement of medical study, will be received. For those who have a diploma of A.M., attendance on anatomy during the fourth session of the curriculum of arts, and on a full course of chemistry, will be considered as one medical session. Every candidate must have attended for two years an hospital containing 100 beds; and, during three months, a dispensary for the compounding of medicines. Previous to the medical examination, candidates not having the degree of A.M. will be required to translate a passage from Celsus.

The preceding regulations will be enforced in the case of all students who commenced their medical studies subsequent to October 1st, 1840. But practitioners who possess a license or diploma from any of the Royal Colleges of Physicians or Sur-

geons, or from the Apothecaries' Company, and who have been engaged five years in the practice of medicine, will be admitted to examination on producing their license or diploma, along with satisfactory evidence of good moral character, and of having studied the classics. Practitioners who commenced their medical studies before October 1840, and who have not been in practice for five years, will be exempt from a year's residence at King's College. Fees, £26:5:6.

N.B. The University and King's College is the only institution in Aberdeen which has a legal power of granting degrees in medicine.

UNIVERSITY OF ST. ANDREW'S.

DEGREE OF DOCTOR OF MEDICINE. Every candidate for a diploma in medicine shall produce satisfactory evidence:—1. Of unexceptionable moral character; 2. Of having had a liberal and classical education; 3. Of having completed the twenty-first year of his age. Fellows, members, and licentiates of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin; of the Royal College of Physicians of London; of the Faculty of Physicians and Surgeons of Glasgow; and of the London Apothecaries' Company, are eligible as candidates for the degree of doctor of medicine, on producing their diploma or license. Candidates not holding any of the above qualifications must produce proof that they have attended lectures delivered by professors in some university, or by fellows of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, or Dublin, for four complete winter sessions, or for three winter and three summer sessions, on the following branches:—Anatomy, two courses of six months each; practical anatomy or dissections, twelve months; physiology, one course of six months; chemistry, one course of six months; practical chemistry, one course of three months; materia medica and pharmacy, one course of three months; midwifery and diseases of women and children, one course of three months; surgery, one course of six months; clinical surgery, one course of six months; practice of medicine, one course of six months; clinical medicine, one course of six months: and that they have diligently attended, for at least two entire years, the medical practice in some public hospital in Great Britain or Ireland, containing not less than one hundred beds, and having a regular establishment of physicians, as well as surgeons.

EXAMINATIONS. *Examiners for Degrees in Medicine:* Dr. George E. Day, Mr. Arthur Connell, and Dr. William Piper. *Assistant-Examiner:* Dr. Andrew Anderson. The examinations commence on the first Wednesday in May, and the third Wednesday in October. The graduation fee is twenty-five guineas. In the event of a candidate being found unqualified, he shall forfeit five pounds of the graduation fee, which will be accounted for to him, when he passes his examination at a subsequent trial. Candidates can only be admitted to examination at other periods by a special grace of the Senatus Academicus. The graduation fee in this case is fifty guineas. The examination extends over two days, and is partly in writing and partly oral. On the first day, candidates give a written translation of a passage from a Latin medical author, and are examined in the elements of chemistry, in materia medica, and in anatomy and physiology. On the second day, they are examined in pathology and the practice of medicine, in the principles of surgery, and in midwifery. The degree is conferred on the following morning by the Rector, in the Hall of the Public Library of the University; and the diplomas are signed by the Principals and Professors of the University. Every candidate is required to present himself for registration to the Secretary, on or before the day preceding the examination, and to communicate by letter with the Professor of Medicine, at least a fortnight previously, stating what diploma or certificates he intends to produce.

The following are the MEDICAL SCHOOLS in Scotland:—

EDINBURGH.—UNIVERSITY.

—SURGEONS' HALL.

GLASGOW.—UNIVERSITY.

—ANDERSONIAN UNIVERSITY.

—ROYAL INFIRMARY.

ABERDEEN.—UNIVERSITY AND KING'S COLLEGE.

—MARISCHAL COLLEGE.

UNIVERSITY OF EDINBURGH.

Prospectus not received.

SURGEONS' HALL, EDINBURGH.

WINTER SESSION. Chemistry. Dr. George Wilson. First course, £3:5; second, £2:4; perpetual, £5:5. Surgery. Dr. R. J. Mackenzie and Mr. Spence. First course, £2:4; and £5:5.

Natural Philosophy. Dr. George Lees. Fee, £3:3.
 Clinical Medicine. Dr. A. Halliday Douglas; Tuesday and Friday, at twelve.
 Clinical Surgery. Dr. Dunsmure; Tu. and F., at twelve.
 Anatomy. Mr. John Struthers. Fees, £3:5; £2:4; £5:5.
 Materia Medica and Dietetics. Dr. Douglas MacLagan.
 Midwifery. Dr. Campbell. Fees, £3:5; £2:4; and £5:5.
 Practice of Physic. Dr. Alex. Wood and Dr. W. T. Gairdner. Fees, £3:5; £2:4; and £5:5.
 Analytical Chemistry. Dr. Wilson. Fee, £2 per month; or £10 per winter session.
 Practical Chemistry (three months). Fee, £3:3.
 Practical Anatomy. Mr. John Struthers, assisted by Dr. Greig; nine till four. Fee, £3:3; with demonstrations, £4:4.
 Anatomical Demonstrations. Mr. John Struthers. Fee, £2:2.
 Royal Infirmary. Fees, perpetual, £12:17; annual, £5:7:6; half-yearly, £3:5:6; quarterly, £1:13.
 Edinburgh Maternity Hospital. Fee, six months, £1:3.
 SUMMER SESSION. Natural Philosophy. Dr. Lees.
 Medical Jurisprudence. Dr. Rutherford Haldane.
 Midwifery. Dr. Keiller, Dr. J. Matthews Duncan.
 Clinical Surgery. Dr. Dunsmure.
 Practical Anatomy, with Demonstrations. Mr. John Struthers, assisted by Dr. Greig.
 Practical and Analytical Chemistry. Dr. Wilson.
 Operative Surgery. Mr. John Struthers.
 Pathological Anatomy. Dr. W. T. Gairdner.
 The introductory address will be delivered by Dr. R. J. Mackenzie, on Wednesday, November 2, at 2 p.m.
 The above courses of lectures qualify for examination at the various examining boards in Great Britain and Ireland.

UNIVERSITY OF GLASGOW.

WINTER SESSION. FACULTY OF MEDICINE. Surgery. Dr. Laurie. Fee, £3:3.
 Practice of Physic. Dr. John Macfarlan. Fee, £3:3.
 Chemistry, Practical Chemistry, and Analytical Chemistry. Dr. T. Anderson. Fees, Chemistry, £3:3; Practical Chemistry, £2:2; Analytical Chemistry, £4:4.
 Anatomy, Anatomical Demonstrations, and Practical Anatomy. Dr. Allen Thomson and Dr. Wm. Aitken. Fee, £3:3.
 Botany. Dr. Walker Arnott; at twelve. Fee, £3:3.
 Medical Jurisprudence. Dr. Rainy. Fee, £3:3.
 Materia Medica. Dr. John Couper. Fee, £3:3.
 Midwifery. Dr. Pagan. Fee, £3:3.
 Institutes of Medicine. Dr. Buchanan. Fee, £3:3.
 Lectures on the Eye. Dr. Mackenzie. Fee, £2:2.
 Royal Infirmary, visit at two.
 Clinical Lectures at three.

ANDERSONIAN UNIVERSITY, GLASGOW.

WINTER SESSION. Principles and Practice of Medicine: Dr. Andrew Anderson. Fees, £2:2, and £3:3.
 Surgery: Dr. R. Hunter. Fees, £2:2, and £3:3.
 Midwifery: Dr. Paterson. Fees, £2:2, and £3:3.
 Descriptive Anatomy: Dr. M. S. Buchanan and Dr. George Buchanan. Fees, £2:2, and £3:3.
 Anatomical Demonstrations: Dr. M. S. Buchanan and Dr. George Buchanan. Fees, £2:2, and £3:3.
 Practical Anatomy: Dr. M. S. Buchanan and Dr. George Buchanan, daily.
 Institutes of Medicine: Dr. E. Watson. Fees, £2:2, and £3:3.
 Chemistry, and Practical Chemistry: Dr. F. Penny. Fees, £2:2, and £3:3.
 Laboratory Manipulation: Dr. F. Penny, daily.
 Materia Medica: Dr. Easton. Fees, £2:2, and £3:3.
 Medical Jurisprudence: Dr. Crawford. Fees, £2:2, and £3:3.
 Natural Philosophy: Dr. Taylor. Fees, £2:2, and £3:3.
 Mathematics: Mr. Laing. Fees, £2:2, and £3:3.
 Royal Infirmary, £8:8, perpetual, with Clinical Lectures.
 Eye Infirmary, £2:2, for six months. Lying-in Hospital, 10s. 6d, for six months. Dressers are appointed, without fee, from the students.
 SUMMER SESSION. Botany: Dr. Joseph Bell. Fees, £2:2, and £3:3.
 Midwifery: Dr. Paterson. Fees, £2:2, and £3:3.
 Practical Chemistry: Dr. Penny. Fees, £2:2, and £3:3.
 Anatomical Demonstrations and Surgical Anatomy: Dr. M. S. Buchanan and Dr. George Buchanan. Fees, £2:2, and £3:3.

Practical Anatomy: Dr. M. S. Buchanan and Dr. George Buchanan, daily. Fees, £2:2, and £3:3.
 Fee for each class, £2:2.

ROYAL INFIRMARY, GLASGOW.

PHYSICIANS: Dr. Weir, Dr. Ritchie, Dr. Easton, Dr. Bell, and Dr. McGregor. SURGEONS: Dr. Lawrie, Dr. A. Buchanan, Dr. Hunter, Dr. Fleming, and Mr. Wm. Lyon. MEDICAL SUPERINTENDENT: Dr. J. C. Steele.

FEES. Perpetual, £8:8; for one year, £5:5. Perpetual to those who have previously entered: For one year, £3:13:6; for six months to holders of surgical diplomas, £2:2.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

Prospectus not forwarded.

MARISCHAL COLLEGE AND UNIVERSITY, ABERDEEN.

FACULTY OF MEDICINE. WINTER SESSION. Practice of Medicine: Dr. Macrobin. Fee, 3:3.

Surgery: Professor Pirrie. Fee, £3:3.

Midwifery, and Diseases of Women and Children: Dr. Dyce. Fee, £3:3.

Anatomy: Professor A. J. Lizars. Fee, £3:3.

Institutes of Medicine: Dr. Ogilvie. Fee, £3:3.

Practical Anatomy and Anatomical Demonstrations: Professor A. J. Lizars and Dr. Beveridge. Fee, £2:2.

Chemistry: Dr. Clark and Mr. Brazier. Fee, £3:3.

Practical Chemistry: Dr. Clark and Mr. Brazier. Fee, £3:3.

Materia Medica: Dr. Henderson. Fee, £3:3.

Natural History: Dr. Nicol. Fee, £3:3.

Janitor's fee for each class, 2s. 6d.

SUMMER SESSION. Botany: —. Fee, £2:2.

Medical Jurisprudence: Dr. Ogston. Fee, £2:2.

Practical Anatomy and Demonstrations: Professor A. J. Lizars and Dr. Beveridge. Fee, £2:2.

Histology: Dr. Beveridge. Fee, £2:2.

Practical Chemistry: Dr. Clark and Mr. Brazier. Fee, £3:3.

Hospital practice daily, at the Royal Infirmary. Perpetual fee to the hospital, £8:8. The resident physicians' and surgeons' assistants are selected from the senior students. Fee, £25, which includes bed and board. Dresserships are conferred on students without fee.

LICENSING BODIES IN IRELAND.

The following institutions grant medical diplomas and degrees in Ireland:—

DUBLIN.—QUEEN'S UNIVERSITY.

—ROYAL COLLEGE OF SURGEONS.

—KING'S AND QUEEN'S COLLEGE OF PHYSICIANS.

—APOTHECARIES' HALL.

THE QUEEN'S UNIVERSITY IN IRELAND.

REGULATIONS. Every candidate for the degree of M.D. shall produce a certificate from the Council of one of the Queen's Colleges that he has passed matriculation examination for arts, and has been admitted a matriculated student of the College in the Faculty of Medicine. The curriculum shall extend over a period of at least four years, and shall be divided into two periods of at least two years each. The first period shall comprise the following lectures:—Chemistry, Botany, and Zoology; Anatomy and Physiology; Practical Anatomy; Materia Medica and Pharmacy; six months each. The second period shall comprise:—Anatomy and Physiology; Practical Anatomy, Theory and Practice of Surgery; Midwifery and Diseases of Women and Children; Theory and Practice of Medicine; six months each: Medical Jurisprudence, three months. In addition, candidates shall have attended during the first period: Practical Chemistry, three months; Medico-Chirurgical Hospital, containing at least sixty beds, with Clinical Lectures, six months. And during the second period: Practical Midwifery, six months; Practical Pharmacy, three months; Medico-Chirurgical Hospital, with Clinical Lectures, eighteen months.

Candidates shall pass two examinations: the first comprising the subjects of the first period of the curriculum; the second comprehending subjects of the second period. Students may present themselves for their first examination at the termination of the first period of the curriculum, or at any after period to be fixed by the senate previous to their undergoing the second examination.

By the charter, candidates must have attended at least one-third of the lectures in one of the Queen's Colleges. For the remainder, certificates will be received from the lecturers in universities, colleges, or schools recognised by the University.

Candidates must have attended in one of the Queen's Colleges, lectures on one modern language, and on natural philosophy for six months; and they will be examined in these subjects.

The examinations will be conducted principally by printed papers, to which written answers shall be given; but the examiners shall also be at liberty to add *vis à voce* examinations on the subject of the written paper.

The above regulations will be binding on all students commencing their medical studies on or after the 1st October, 1853; but students already engaged in their medical studies may either complete their courses according to the Ordinance of 30th June, 1850, or according to the present ordinance.

EXAMINERS FOR THE YEAR. Chemistry: Dr. Edmund Ronalds. Anatomy and Physiology: Dr. Charles Croker King. Medicine: Dr. John Banks. Surgery: Dr. James S. Hughes. Materia Medica, Pharmacy, and Medical Jurisprudence: Dr. Aquilla Smith. Midwifery, and Diseases of Women and Children: Dr. Henry L. Dwyer. Zoology and Botany: Dr. George Dickie.

ROYAL COLLEGE OF SURGEONS, IRELAND.

President: William Hargrave. **Vice-President:** Charles Benson. **The Council:** Sir Philip Crampton, Bart.; Alexander Read; Arthur Jacob; A. Ellis; R. C. Williams; R. Adams; J. Barker; W. Colles; J. H. Power; Edward Hutton; J. Macdonnell; H. Irvine; J. S. Hughes; Robert Pentland; Robert Mayne; Richard G. H. Butcher; Augustus E. Tabuteau; Samuel G. Wilmot. **Honorary Secretary of the College:** Edward Hutton. **Secretary of the Council:** Henry Maunsel. **Court of Examiners:** T. Rumley; J. Smyly; C. Fleming; O'Brien Bellingham; R. Tuohill; Thomas Byrne; Francis Battersby. **Examiners in Midwifery:** Robert Johns; Alfred McClinton; Samuel L. Hardy.

PROFESSORS. Anatomy and Physiology: Arthur Jacob. Descriptive Anatomy: J. H. Power. Surgery: H. Porter and W. Hargrave. Medicine: C. Benson. Chemistry: W. Barker. Materia Medica: R. C. Williams. Midwifery: T. Beatty. Medical Jurisprudence: T. P. Geoghegan. Botany: A. Mitchell.

Fellows of the College are members of the Corporation, and are admitted by examination; letters testimonial are granted to licentiates; and a diploma in midwifery to fellows and licentiates educated and examined in that branch of surgery.

FELLOWSHIP. Candidates must be twenty-five years of age, and must give proof of liberal preliminary education, and good conduct. They must produce certificates of surgical studies for six years (three of which must be in Dublin), and also of practice as house-surgeon or dresser in an hospital; as well as of attendance on hospitals, lectures, and dissections, as required from licentiates; with the addition of Botany, Comparative Anatomy, and Natural Philosophy. **FEE, £20 : 5**; if the candidate be a licentiate, £10 : 10.

LETTERS TESTIMONIAL. Candidates are required to produce certificates of preliminary classical education; of four years' professional study (three of them in metropolitan schools), also three years' attendance on hospital lectures and dissections. **FEE, £21.**

MIDWIFERY DIPLOMA. Candidates must be fellows or licentiates, and must produce certificates of attendance on midwifery lectures and practice, with proof of having attended thirty cases of parturition.

Candidates for the Fellowship and Letters Testimonial are publicly examined on two separate days, in anatomy, physiology, surgery, practice of medicine, and pharmacy. The examiners are elected by a sworn jury of the Council appointed by lot, teachers being ineligible.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Visitors: The Lord High Chancellor of Ireland; the Lord Chief Justice of the Queen's Bench; the Lord Chief Justice of the Common Pleas; the Chief Baron of the Exchequer. **President:** W. F. Montgomery. **Vice-President:** Aquilla Smith. **Censors:** Thomas Brady; William Stokes; Aquilla Smith; James Foulis Duncan. **Treasurer:** John Mollan. **Registrar:** W. E. Steel, 15, Hatch Street. **Professor of Midwifery:** W. F. Montgomery. **Professor of Medical Jurisprudence:** Thomas Brady. **Examiners in Midwifery:** W. O'Brien Adams; Henry Law Dwyer; Fleetwood Churchill. **Inspectors of Apothecaries' Shops:** Thomas Brady; Aquilla Smith; James Foulis Duncan; W. E. Steel.

Physicians practising in Dublin, and within seven miles thereof, and those attached to county infirmaries and prisons in Ireland, are required by the charter and statutes to possess the license of the college.

Candidates for the license who have completed the following

course of education are admissible to examination: Anatomy, Chemistry, Practice of Medicine, Materia Medica, Institutes of Medicine and Midwifery, Demonstrations and Dissections, of each six months. Botany, Medical Jurisprudence, of each three months. Medico-Chirurgical Hospital, two years and a half; and Lying-in Hospital six months. Graduates in Medicine of any university in the United Kingdom, and surgeons of four years' standing or upwards, are admissible to examination on producing their diplomas. Surgeons under four years' standing are required to have attended Botany, Institutes of Medicine, and a Lying-in-Hospital. Candidates undergo two days' examination on the above subjects, except medical graduates and surgeons of seven years' standing, who are examined in the subjects of the second day only, viz.: Practice of Medicine, Institutes of Medicine and Midwifery. Surgeons who are A.B.'s, in addition to these subjects, are examined also in Botany and Materia Medica. Members of any Apothecaries' Company are ineligible for admission. Licentiates of three years' standing, who are graduates of the Universities of Oxford, Cambridge, or Dublin, are alone eligible to the Fellowship.

FEES. License, £30; stamp duty, £15; Fellowship, £20; stamp duty, £25.

APOTHECARIES' HALL OF IRELAND.

EDUCATION OF APOTHECARIES. Every candidate must undergo two separate examinations, one for the certificate of apprenticeship, the other for the license to practise.

Every candidate for the certificate of apprenticeship will be examined in the following books. In Latin: the Catiline War of Sallust, and the first three books of the *Æneid* of Virgil. In Greek: the Gospel of St. John, and the first twenty Dialogues of Lucian, or the first two books of Homer's *Iliad*. In French: Telemachus, or the History of Charles XII. In Science: the first two books of Euclid and Algebra, to the end of simple equations.

Every candidate for the license to practise must lay before the court the certificate of apprentice; the indenture of apprenticeship, enrolled according to Act of Parliament, and bearing the certificate of a good moral character, and of having fulfilled the period of his apprenticeship; certificates, that he has diligently attended at least one course of lectures on each of the following subjects at the Apothecaries' Hall, or some other recognised school of medicine: Chemistry, Anatomy and Physiology, six months; Practical Chemistry, Botany, and Natural History, three months; Materia Medica, Demonstrations and Dissections, Theory and Practice of Physic, Surgery, Midwifery, and the Diseases of Women and Children, six months; Medical Jurisprudence, three months.

Attendance for the entire period of eighteen months on the medical and surgical practice in an hospital or hospitals, recognised by the Court. Also, a certificate of having assisted in at least thirty cases of midwifery practice, twenty of which must be attended in a recognised hospital.

The examination for the license to practise as an apothecary will be in Chemistry and General Physics; Pharmacy, Theoretical and Practical; Materia Medica and Therapeutics; Natural History and Medical Botany; Anatomy and Physiology; the Theory and Practice of Medicine; Midwifery; Medical Jurisprudence.

Graduates in Medicine of any of the British or Irish Universities, or those who possess letters testimonial from any of the Royal Colleges of Surgeons in Great Britain or Ireland, will be admitted to examination for the license on producing proof of three years' legal apprenticeship to a qualified apothecary practising with open shop in Ireland, and of a professional education equal to the curriculum prescribed by the Council.

The examination for the license to act as assistant to an apothecary is confined to Chemistry and Theoretical and Practical Pharmacy. The candidate for the assistant's license may present himself for examination at the termination of three years' apprenticeship.

The Court of Examiners sits every Friday at two o'clock, and examines candidates in the order in which their names appear on the list. Candidates must lodge their testimonials a clear week before the day of examination. A rejected candidate cannot be readmitted to examination until the end of six months.

An examination of apothecaries' apprentices takes place at the Hall, on the first week in May, annually, upon some subject in Pharmaceutical or Pathological Analysis, publicly announced at the commencement of the previous winter session, and a prize of five guineas is awarded to the successful competitor.

MEDICO-METEOROLOGICAL OBSERVATIONS

Taken for the Association Medical Journal.

NEWS AND TOPICS OF THE DAY.

MEDICAL SOCIETY OF LONDON. The following papers are announced as intended to be read at the ordinary meetings of this society.

Saturday, October 15th. W. Coulson, Esq., "On Suppuration of the Joints from Infection of the Blood."

Saturday, October 22nd. F. Sibson, M.D., F.R.S., "On Pericarditis."

Saturday, October 29th. F. W. Mackenzie, M.D., "On the Source of Hæmorrhage in Partial Separation of the Placenta."

Saturday, November 5th. J. R. Cormack, M.D., "On Cholera."

SANITARY EFFORTS IN GLASGOW. At a recent meeting of the Police Board, the following letter was read, and referred to a Committee:—

"TO THE POLICE COMMITTEE OF THE TOWN COUNCIL OF GLASGOW.

"4, Athole Place, Glasgow, Sept. 26, 1853.

"GENTLEMEN,—I beg respectfully to direct your attention to the subjoined resolution of the Medico-Chirurgical Society of Glasgow, passed at their meeting held on the 9th of August, and ordered by them to be submitted respectfully to you, in the hope that it may prove serviceable to their fellow-citizens.—I have the honour to be, gentlemen, with much respect, your most obedient servant,

"ANDREW BUCHANAN, M.D.,

"President of the Medico-Chirurgical Society of Glasgow."

Resolution adopted by the Medico-Chirurgical Society of Glasgow on 9th August, 1853:—

"That the society are of opinion that the practice at present adopted in this city of having permanent depositories of filth, such as dunghills, or subterraneous caverns, is not only disgusting and offensive, but injurious to the health of the inhabitants; and that the practice adopted in many other cities—that of removing, every evening or morning, the impurities which have accumulated during the preceding twenty four hours—appears to the society to be much superior; and the society direct their President respectfully to communicate these views to the Police Committee of Council for the benefit of their fellow-citizens."

"Extracted from Minutes by

"THOS. WATSON, M.D., Sec. Med.-Chir. Society."

THE AZTEC CHILDREN. The *Athenæum* of October 1st quotes from the proceedings of a meeting of the Boston Society of Natural History, held on January 1st, 1851, some observations regarding the Aztec children.

"Dr. J. M. Warren read a paper containing some observations upon two remarkable Indian children, a boy and girl, from Central America, who had lately been exhibited in Boston, known as the 'Aztec children'. He had been led by his examination of them to the following conclusions:—

"1. That these children are possessed of a very low degree of mental and physical organisation, but are not idiots of the lowest grade. 2. That they probably originated from parents belonging to some of the mixed Indian tribes. 3. That they do not belong to a race of dwarfs, because history teaches us the truth of the doctrine stated by Geoffroy St. Hilaire, that dwarfs cannot perpetuate their kind.

"At the conclusion of Dr. Warren's paper, a letter was read by the Secretary, addressed to him by Mr. E. G. Squier, corroborating Dr. Warren's view of the true character of the so-called 'Aztec children', containing the following statement:—

"The Commandant of the Port of La Union, in the State of San Salvador, Central America, informs me that they were born somewhere near the town of Santa Ana, in that State, of parents, one of whom certainly, if not both, was dwarfed or deformed and imbecile. The Indians residing in the vicinity of Santa Ana are civilised, and centuries ago adopted Spanish customs and the Spanish language. So far as I could discover from a few words of their ancient language which came into my possession, they belong to the Choluctecan or Chorotegan stock, which, before the conquest, extended over a part of San Salvador, Honduras, and Nicaragua, but which was chiefly concentrated around the Gulf of Fonseca."

MEDICAL BENEVOLENT COLLEGE. The Council met for the first time on Wednesday last, in their new and spacious offices, 37 Soho Square, on which occasion it was decided that the Second Festival, which is to be under most distinguished patronage, should take place in April next.

MEDICAL ADVERTISING. "There can," says the *Dublin Medical Press*, "be no doubt that medical advertisements display more unblushing rascality than any other class of advertisements whatever. A medical pauper may work in this way to escape starvation, but he has no right to make the title of physician infamous by such use of it as the following:—

"CHEMISTS AND DRUGGISTS. A physician is open to an engagement to practise; would not object to do so at the establishment. He is of mature age and experience, not dependent upon his profession, but wishes to form a home practice. Address M. D., Post-office, Plymouth." From the *Plymouth Journal*, September 6th.

"TO CHEMISTS AND DRUGGISTS. (MEDICAL ADVICE GRATIS.) A physician, of mature age, not for the sake of gaining experience, which he has already acquired, intends commencing in Plymouth, on the same gratuitous system which has proved so lucrative both to physicians and druggists. He is anxious to make an immediate arrangement with a respectable tradesman, and will be satisfied with a smaller per centage on his prescriptions than has hitherto been given. Minor operations in surgery will be performed. Address, Medicus, *Journal Office*." *Id.*

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

FILLITER, William, M.B., appointed Surgeon and Apothecary to the Marylebone Workhouse, in the room of W. Squire, Esq., resigned.

*GAIRDNER, W. T., M.D., appointed Physician to the Royal Infirmary of Edinburgh on the 10th instant. By this appointment, the offices of Pathologist and Assistant Physician, held by Dr. Gairdner, have become vacant.

*MICHAEL, W. H., Esq., appointed Officer of Health for Swansea, by the Board of Health of that burgh, for one year, at a salary of £150.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLII.

LONDON: FRIDAY EVENING, OCTOBER 21, 1853.

NEW SERIES.

TO CORRESPONDENTS.

THE ANNUAL SUBSCRIPTION to the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION is £1:1:0. Legally qualified members of the profession are eligible as members. Irregular practitioners are not admitted; and improper members have from time to time been expelled. Gentlemen wishing to join the Association can obtain full information from the General Secretary (J. P. Sheppard, Esq., Worcester), from any of the local Secretaries, or from the Editor of the Journal. Every member is entitled to receive weekly, post free, the ASSOCIATION MEDICAL JOURNAL, which is the organ of the body.

ADVERTISEMENTS for the ASSOCIATION JOURNAL ought to be addressed to Mr. Honeyman, the Publisher, and not to the Editor. They are received at the office, 37, Great Queen Street, Lincoln's Inn Fields.

LETTERS from numerous correspondents have been received regarding the injustice and defects of the Vaccination Act, and on various points in relation to it. We shall insert as many of these communications as possible, endeavouring to represent by our selection all opinions. We are, from the large amount of space occupied by the list of members, obliged to defer letters on Chloroform in Parturition, on Medical Ethics, and a variety of other subjects. For the same reason some important articles in the PERISCOPE REVIEW are also postponed.

THE NUMERICAL STRENGTH OF THE ASSOCIATION.

We have great pleasure in publishing this day a complete List of the Members of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION for the present year.

It appears that the total number of members for 1853 is 1926; and that their distribution and percentage to the whole profession is as follows:—

	Medical men.	Members of Assoc.	Per cent. of members.
England - - -	9315	1748	17.8
Wales - - -	315	112	35.5
Scotland - - -	1623	47	2.8
Ireland - - -	2100	4	—
Isle of Man and Channel Islands - - -	62	7	17.7
Foreign Countries - - -	—	8	—
Total - - -		1926	

The percentage of the whole profession belonging to the Association is more minutely exhibited in the following table:—

ENGLAND.	Medical men.	Members of Assoc.	Per cent. of memb.
Bedfordshire - - -	68	9	14.3
Berkshire - - -	93	33	35.5
Buckinghamshire - - -	67	8	12

Total members of Association - 1926

The following Table represents the distribution of old and of new members, and of councillors. The Association, it will be seen, is represented in all the 40 counties of England; in all the 12 counties of Wales, except Cardigan; and in 14 of the 33 counties of Scotland. The Channel Islands, the Isle of Man, and Foreign Countries, also acknowledge our fraternity. The names of the counties are arranged alphabetically. In subsequent remarks we shall consider the counties geographically, in their parliamentary relations, and with reference to a consolidation and organisation of the power of our Association. To-day we content ourselves with presenting plain facts for the contemplation and encouragement of those who desire to see the Association embracing every respectable practitioner in the kingdom, and the medical profession enjoying its due influence in the State.

Total	1466	466	1926	310	16
-------	------	-----	------	-----	----

The new members of 1853 are distinguished in the subjoined List by *n*: and members of the General Council by *c*. The number of members on the roll at the 31st of December, 1852, was 1466; and since that time there have been added 460, making the total number of members for the year 1853, up to the present date, 1926.

It will be seen that there are 310 members of the General Council; and that all of them belong to the 1466 old members, except Sir J. L. Bardsley and Dr. Lyon, old members, who rejoined the Association during the year.* If the new members had a due share of their number in the Council, it would augment that body (already nearly inert from its inordinate size) to 408.

All gentlemen who have entered the Association since the 31st of December 1852, are marked as new members. Some of them, however, at some previous period belonged to the Association. To have, by a special mark, distinguished all of this class, would have been impossible from the deficiency of documents to which we have access; so that it has appeared simpler to denote by one sign all new members who have entered or re-entered during 1853. About thirty old members have become new members; and among them we can at the moment name Sir James Bardsley and Dr. Lyon, of Manchester; Mr. Halliday, of Seacombe; Mr. C. L. Prince, of Uckfield; Professor Bowman, and Mr. White Cooper, of London. As these gentlemen did not belong to the Association in 1852, they are, along with others similarly situated, embraced in the general catalogue as new members.

To-day we have given in a few pages the results of much labour and irksome calculation. Our object has been to bring forward the facts in as simple a form as possible; knowing that we could not present matter which would be more generally acceptable, and eventually more useful. Commentaries and reflections we reserve for another and an early opportunity.

As new members are every day joining our ranks, we propose to print a supplementary list before the close of the year.

* At the Swansea meeting, the Council was, in accordance with the usual practice at annual meetings, re-elected, with the addition of a few names. The gentlemen so added this year were twelve in number, viz.: Dr. Eves, Cheltenham; E. Ingram, Esq., Boston, Lincolnshire; D. Everett, Esq., Worcester; R. H. M'Keand, Esq., Manchester; Thomas Mellor, Esq., Manchester; John Robertson, Esq., Manchester; William Smith, Esq., Manchester; Sir James L. Bardsley, M.D., Manchester; Dr. Eason Wilkinson, Manchester; Dr. Whitehead, Manchester; Dr. Lyon, Manchester; William Rowland, Esq., Swansea.

THE PREVALENT TREATMENT OF DISEASE.

It must have been obvious to the most superficial observer of the course of diseases in this country, that in the case of many of them, either their type or their treatment have undergone so great modifications, as entirely to change their aspect, their progress, and their termination. Without being enunciated in learned tomes, gradually impressing itself on the professional mind, the axiom has attained universal credence, and has been most generally acted upon, that acute inflammatory attacks of disease are becoming more and more rare; that in place of acute peritonitis, we have neuralgia and spasmodic abdominal affections; while congestive and subacute chest affections have almost entirely superseded acute pneumonia and pleuritis. The lancet has been replaced by ammonia, and leeches by agents tending rather to derive blood from internal organs, and direct the circulation to the external portions of the body, than to abstract it from the general system.

To our mind, it speaks well for the professional intellect of this country, that while few great and learned authorities have laid down general laws subversive of ancient faith on these points in medical practice, still everywhere we find a just appreciation of their bearing and import; and,

instead of the disease, we find the patient to be the chief object of the medical attendant's care and solicitude. We have with the greatest pleasure noticed abroad in the medical world, a desire to form just conclusions, not so much from the experience and writings of our forefathers in physic, as from the living daily knowledge acquired by each practitioner of the healing art at the bedside of his patient. Bleeding, leeching, and blistering, are not adopted because it is so written in our worthy "Thomas's Practice of Physic"; but arguing logically on the facts within his knowledge, the practitioner draws just conclusions from the state of increased action, of depression, or of congestive action, and directs his remedies accordingly. Holding these views ourselves, we cannot but hail with pleasure the appearance of any work,*—however little it may add to our previous knowledge, and however much it may be but a record of already well recognised facts—which develops these changes in the character of disease, and lays down laws for treatment in accordance with the varieties of etiology and semeiotics everywhere observable.

It is only matter of regret to us that leading professors should be so ignorant of the state of medical practice in the provinces, as to write as if the times still continue when in surgeries twenty persons were collected for

* The Prevalent Treatment of Disease. By F. G. ...

phlebotomy on a Sunday morning, it being considered an absolute necessity to be bled in the "spring and fall." Bleeding is now rarely practised; and when we take into account the more robust health and less impaired condition of the persons who fall under the country surgeon's care, we may venture to say, even with less comparative frequency than in the hospital practice of Professor Skey himself. Active purgatives, as a means of lessening febrile action, are of course resorted to upon proper occasions; but it is almost alone in the cases where a man becomes his own physician that the inordinate use of those measures so deprecated by the professor is to be found.

We cannot but wish that in all medical writings there should be the most careful exclusion of aught tending in the eyes of the public to convey the impression that the majority of the profession were not *au courant* with the state of medical knowledge; and most jealously should every author endeavour to avoid, by inference or assertion, directing attention to himself as the "*fons et origo*", and the only repository of sound practice.

We believe that hospital surgeons, and physicians in great towns, are not the men to whom we must look for the exposition of country practice, the diseases there most prevailing, or the forms those diseases assume. True it is that there are no schools so capable as the metropolitan hospitals of teaching by practical demonstration how a limb should be removed; but for true clinical surgery, where the lessons to be learnt are entirely conservative, we have long inclined to the opinion that it is in the practice of the country surgeon, the attendant on extensive works or manufactories, that the art, if not the science, the practice, if not the principles of surgery are to be learnt by the student. Is it at the heels of professors, and over the heads of surrounding fellow students getting a glimpse of fractures enveloped in the thousand and one appliances which a large hospital affords, that the treatment of surgical diseases can be learned? No. It is in the lonely cottage far from home, with no complicated splints, leg rests, or fracture beds, that the future surgeon must learn his profession, and be called on to treat those serious accidents which the records of London Hospitals point to as almost inevitably causing loss of life or limb.

How little prepared would be the new member of the college, who had learned clinical surgery only at the London or Edinburgh Hospitals, without ever having had the opportunity of trusting to his own resources, or seeing thoroughly the progress of a case of compound fracture, to take upon himself the charge of the every day practice of the country surgeon, who must learn to act promptly and for himself in all emergencies. Rather should our sons have a few months' drilling in the true schools for clinical surgery, which iron and copper works, and large manufactories, railways, and docks afford, than the elaborate disquisitions, (misnamed clinical,) which may fill the mind with learned names, but do little to cultivate the hand, or confer practical information, ready for immediate use in those minutiae that make up the sum of successful surgical practice, where such practice emulates the patient and conservative, rather than the brilliant but destructive; which seeks rather to preserve a shattered limb by perhaps months of attention and watching, than at once by its removal to cut the gordian knot of difficulty. What dare not be attempted in a metropolitan hospital, may with impunity be left to nature's *vis medicatrix* in the poor man's healthful hill-side cottage.

We advisedly affirm that except where the accident is so severe as to cause fatal collapse, deaths from compound fracture are in the country the exception to a general rule; and that Mr. Skey, in condemning in so wholesale a manner the treatment by active bleedings and purgatives, fights with a shadow, and rebuts, with evidence and argument, practices which scarcely exist, and to which there is sufficient answer in the great success which attends the practitioner in the treatment of these severe injuries.

We have often had occasion to regret that country surgeons who might add from their note books so many records of successful cases, illustrative of the curative powers of nature, should from a false fear of ostentatious display, add so little to the medical literature of the day. They are thus equally unjust to themselves as individuals, to the Association, of which they form a part, and to the true and rightful interests of medical science, which can never assume its place, until it has accumulated from such sources stores of information upon many points on which we are still far from certain proof.

As illustrative of the country surgeon's duties, we are reminded of a case where on the first night of this year, a colleague was summoned at midnight to see a woman who had just fallen down stairs. She had no one in the house but her paralytic husband, who was unable to leave his chair by the fireside. Streaming with blood from a compound fracture of the tibia and fibula, these bones protruding many inches from the wound, she succeeded in making herself heard by a neighbour, who ran to procure medical help. Without any assistance, and with no appliances but an apron from which to form bandages, and three or four laths accidentally in the house, and an old pillow, in which to envelope the limb, our friend did what was necessary; and had the pleasure of finding, in a few weeks, the limb entirely restored, without the occurrence of a bad symptom.

Further to exemplify the falsity of the position which the exclusive experience of hospital practice would engender, we can recal many of those accidents of daily occurrence, which the pupil of the country hard-working general practitioner learns to treat for himself, and to treat successfully. On a railway, where 500 or 600 men were employed, we can refer to one accident in which four men were precipitated, (by the breaking of the chain from the skiff in which they were contained,) forty feet down the shaft of a tunnel in course of construction. One of these unfortunates immediately died. Another sustained a fracture (simple) of the thigh, was insensible for some time from wounds of the scalp, and other bruises and injuries, but in five weeks recovered so well as to get drunk, the first day he went out, and again fracture his thigh, which, in another six weeks, was as sound as ever, and as capable of supporting him in his daily work. As though this man were fated to accidents, he subsequently sustained a compound fracture of the leg, which confined him to bed for nine or ten weeks; but, with all these knockings about, he now walks as though his legs had always escaped unscathed from the injuries to which labourers in extensive works are daily liable, and for which the very rudest appliances are of necessity all that are procurable: for it often occurs that the surgeon, in the dead of night, is called on to treat, in coal districts, at the very pit's mouth, the most extensive injuries, with no other apparatus than the cottage of the sufferer affords. The third of these men fractured both legs, had concussion of the brain, and was for many months insane, but became

ultimately so well, that his friends insisted he could not have sustained the injuries.. The fourth fractured the right thigh, dislocated the left ankle, and broke off the outer malleolus, besides sustaining a fracture of four ribs on the left side. These recoveries required much care and time; but they are evidences of the extent to which, in the country, the curative powers of nature in the repair of injury extend, when aided by a scientific use of remedial means.

These cases illustrate the character of every day practice, where fractures, compound and simple, are as plentiful as blackberries; and other surgical misfortunes are equally prevalent. On the line of rail on which they occurred, except those fearful cases where waggons of earth passed over the bodies of the unhappy sufferers, tearing, bruising, and beating the bones to a pulp—only one fatal case occurred during the three years of its construction; and this one, although some days under treatment, was a hopeless one, the pelvis being crushed between two large loaded waggons, and the internal soft parts irretrievably injured.

Erysipelas from injuries in most country places is unknown, and the common occurrences of the surgery, and its merest routine, consist of cases of a character which in a London hospital would endanger life. In the country, such accidents as the tearing of the testicle from its coverings, division of the entire scalp, wounds severing great portions of the soft textures of the face, artificial hair lips, etc., in a list too numerous to mention, hardly occasion to the sufferer the loss of two or three days' work, and fall under the treatment of the pupil or assistant.

We are led to these remarks, not from any wish to make comparisons, to depreciate or deprecate the blessings which flow from the metropolitan and provincial hospitals, but to show that, almost as a matter of course, in the healthy and free air of the country, where there exists no aggregation of the sick, and no concentration of morbid influences, the success attendant on operations, and the favourable results in the way of recovery without loss of members, must be great; and that it is only from the greatest misapprehension that it can be stated that the general practitioner of the present day adopts the bleeding and warm water principles of Dr. Sangrado.

But we must not forget to allude, while upon this subject, to the admirable papers by Mr. Broke Galwey, in the late *Medical Gazette*, on Unhealthy Inflammation; wherein the phases of attack, progress, and treatment of erysipelas, are written of in the manner of the true inductive philosopher,—papers that cannot be too highly commended, and which clearly enunciate all that Professor Skey points out as novel methods of his own in the treatment of disease, and which he untruly considers as opposed to the general practice.

The Lumleian Lectures of Dr. Todd are equally valuable in pointing out the distinction existing in the so-called delirium ferox, and the delirium occurring in the course of those diseases specially marked by blood poisoning. These lessons have not been taught to inattentive ears, for we believe the treatment of fever and diseases of an allied class, is conducted on a more rational and scientific basis at the present than at any former period.

The article by Dr. Risdon Bennett on Pneumonia, in the *ASSOCIATION JOURNAL* of 14th January (p. 29) also recognises in a most instructive manner all that Professor Skey would adduce, as so differing from the ordinary treatment of disease. And if our space would permit, we might

multiply instances and names until we ran the risk of tiring our readers, to prove that what is given as new (although not extensively written on), is generally practised.

We cannot, in this time of cholera specifics, quack nostrums, and catchpenny pamphlets, avoid raising our voice against anything, from whatever quarter, which tends either to disparage our brethren as a body, or as individuals engaged in the practice of medicine. And we would equally oppose the too great advocacy of the stimulating or depressing systems of medicine as applicable to all classes of disease, because we believe that such one-sided teaching has the same evil tendencies as the vulgar puffs of Holloway's ointment or Morrison's pills.

FIRST MEETING OF THE EAST SURREY CHOLERA SOCIETY.

THE meeting for the organisation of this new Society was held at Richmond, on Tuesday the 18th, and is reported in this day's number. The resolutions passed at the meeting must be sought for in the report itself; we need not say that they have our full support. The remarks of Mr. Grainger and Dr. Snow, on the importance of local societies for the observation of epidemic diseases, are, however, very important, and deserve especial notice, as they are well worthy the attention of most of our brethren who practise in rural districts. "The united efforts", says Dr. Snow, "of medical men residing in a district not so densely populated as a large town, nor yet so widely extended as to prevent their meeting together occasionally in a society, may be reasonably expected to furnish a more important contribution to the history of the disease than any which has yet appeared"; and Mr. Grainger, whose knowledge concerning the general principles that should be pursued in observing cholera is second to none, entertains and expressed an opinion precisely similar. It is not by hasty visits to a host of cases by single individuals, and by having those cases reported by individuals independently, that accurate facts concerning cholera can be secured; but it is by obtaining from many practitioners short and correct notes, *taken at the time of observation, and not from memory days afterwards*, of a few cases, and by arranging the whole mass of information thus collected by a society of which all the contributors are members.

A pleasing feature of the meeting to which we refer was the catholic feeling shown by all present. Every member of the Epidemiological Society whose opinions were given on the occasion, seemed as though he were vying with his fellow in affording encouragement to the new society, and in exciting its members to cooperate with the fellows of the Epidemiological Society in their labours.

We cannot conclude without observing that the meetings of the new society are to be confined to no central spot within its boundaries, but are to be held in turn at the principal towns in the district. The next meeting is to be at Wandsworth; and doubtless Rotherhithe, Croydon, Lambeth, etc., will be visited. This system will afford every member an opportunity of attending some of the meetings, and will tend to strengthen the mutual good feeling which was so fully evidenced at Richmond.

ORIGINAL COMMUNICATIONS.

ATMOSPHERIC PHENOMENA IN RELATION
TO THE PREVALENCE OF ASIATIC
CHOLERA.

By J. A. HINGESTON, Esq., Surgeon.

THE Asiatic cholera seems to be associated with a particular state of air, in which it finds its nest for being engendered, fostered, and diffused. This state of the atmosphere is indicated by an overcast sky, a high barometer, a torpid mist, and, for the most part, though not invariably, a high temperature. The mercury in the barometer rises up to thirty inches, although, at the same time, the sky, instead of being Fair, as the instrument denotes, is, on the contrary, shrouded with a veil of clouds—cirro-strati, strati, or indolent cirro-cumuli, of a dull opaque colour. The wind subsides, a calm prevails, and a moisture bedews everything, both in-doors and out. This state of the atmosphere is so unmistakeable, that, when the disease has once broken out, we may be sure of hearing of its increase during the continuance of this sort of weather, and of its diminution the moment a change takes place, and the wind rises, and the barometer sinks, and the mist is dispersed. But the overcast sky and a high temperature are not so requisite to the propagation of the disease as the high barometer, the calm, and the mist. This disagreeable mist is most remarkable: it lies low, rolls off the higher places, descends into the vales and hollows, and settles in corners secluded from thoroughfare and draughts of air. Hence it has been inferred that cholera originates from sinks, sewers, etc.; but, as these offensive recesses are generally set apart by themselves in some enclosed spot, they only afford an undisturbed lodgment for the reception of the poisonous element already afloat in the air, where its malignity becomes condensed and concentrated. Accordingly, in tracing the history of the cholera, we find that it has prevailed chiefly in low, damp, confined localities; that it has appeared at all seasons of the year—midsummer, autumn, and spring, and even in the depth of winter, when the ground has been covered with snow; but that its intensity has been the greatest in the fall of the year, when the weather is moist, or in the middle of the year, when the summer has been wet. It was reported at St. Petersburg, and, I think, at Moscow, during a hard winter; in this country, it broke out in the winter and spring in 1832; in 1849, it prevailed during the summer and the beginning of the autumn; and

this time, 1853, it was first reported in the month of September.

As far back as 1832, Dr. Prout remarked the anomalous elevation of the barometer in connexion with the presence of Asiatic cholera; and at that time, *i. e.*, more than twenty years ago, he attempted to account for it upon the hypothesis of the air being surcharged with a poisonous element of a ponderous nature. There was, he says (*Stomach and Urinary Diseases*, 3rd edition, 1841, p. 22), a positive increase in the weight of the atmospheric air, similar to what might be supposed to be produced by the diffusion of a very heavy gaseous principle through the lower regions of the atmosphere. His conclusion was, that the cause of the phenomenon in question, as well as of the cholera, was a poisonous body analogous to malaria, whose high specific gravity and feeble diffusive powers kept it near the earth's surface, along which it insensibly crept, particularly in low and damp situations. On the 9th of February, 1832, the positive weight of the air suddenly appeared to rise above the usual standard. The apparatus employed was supposed to be out of order, but no error was detected; and the air continued to retain its augmented weight, with more or less obstinacy, for the space of six weeks longer. Now, on that particular day, when the barometer rose so suddenly, and, as it seemed, without a sufficient cause to explain its rise,—on that particular day, the 9th of February, 1832, the first cases of epidemic cholera were reported in England. The wind, which had been previously westerly, veered round to the east, and remained pretty steadily in that quarter till the end of the month. In the summer of that same year, when cholera raged so severely for the first time in Great Britain, the barometer was high, the sky overcast, and the quantity of rain small. A calm prevailed. And, again, in the fatal summer of 1849, I find, in my diary of the weather, that there had been upwards of sixty misty days between the 1st of January and the 31st of August, *i. e.*, one-fourth of the whole period; and that when the mortality was the highest, the weather was dull, thick, and close; the wind from the N.W., with dark masses of clouds, which went out to sea, like the smoke of a large furnace. The elevated position on which I dwell, and my frequent strolls in the surrounding country, gave me ample opportunities of making these remarks with accuracy.

Subjoined is a diagram of the weather during the week that cholera was the worst at Newcastle this year; and what has already been said seems to be borne out, if not demonstrated, by this statistic report.

From August 31st to September 16th, there were 295 fatal cases.

1853.	Wind.	Clouds.	Moisture.	Clear.	Storm, gale, calm.	Temp.	Therm.	Ordinary mortality.	Barometer.	Fatal cases.

The reports of the fatal cases, subjoined at the end of this paper, are from the *Times*. The account of atmospheric changes is from my private diary. It has been collated with those of

the daily papers, and the variations are not great. The same weather seems to have prevailed throughout the country. In reporting the thermometer and barometer, the round

numbers alone are stated. The mark + means *above* the average; the mark — *below*.

It has been said, that the velocity of the air is diminished one-half below its usual ratio; there is an upper, but no lower current of air; and the electricity of the air is negative, during the presence of cholera. I have no personal knowledge of the truth of these facts, but report them only as I have read them.

In this diagram, it appears that the cholera was the worst when the barometer was the highest and the atmosphere the calmest. There was on this occasion, as on the former ones, a certain grey mist, which painters express by the word *scumbling*. As the barometer fell, and the wind rose, and the lazy scud broke away into clouds (*cirro-cumuli*), the mortality fell at the same time from 109 to 80 and 59 respectively, in the course of a couple of days. But, what is most singular, is the fact that, on the present, as on the previous accessions of the disease, the mortality from ordinary causes has been diminished; and, according to the Registrar-General's Report, it has been diminished on this particular occasion two-tenths below the average, *i. e.*, 209 in the 1,000, according to the corrected average. Although it is remarkable that the atmosphere is, during the prevalence of cholera, at once both calm and overcast, and the roads dry if not dusty, yet there is a sticky moisture pervading everything. Housekeepers inform us that articles of diet become more quickly mouldy than usual. The appearance of the air is that of a marshy district, such as I have often witnessed on the low lands of Suffolk and Essex, and the neighbourhood of the Marsh Gate, Lambeth. But this miasmatic atmosphere, instead of being peculiar to those quarters where ague resides, seems to spread universally over the whole land assailed by cholera. The affinity of the phenomena subsisting between cholera and ague is, to say the least of them, very striking. Diarrhoea is the distinctive precursor or concomitant of each; and the collapse, so fatal in cholera, together with the rice-water evacuations, most likely of a poisonous quality, are exaggerated features of its congener, marsh fever. Again, both these diseases haunt damp localities, and exhibit themselves most virulently in the foulest corners; while each has the same tendency to degenerate into low typhus, hectic, and death, or a tedious recovery. This is more than similarity—it is a coincident eventuality; but repeated coincidence implies a law of connexion, perhaps identity.

One pathological remark of some importance ought not to be omitted. We are all of us aware that, during the blue stage of cholera, the urine is either suspended or suppressed. But, during a choleraic period, there is also reigning an epidemic diathesis adverse to the healthy action of the kidneys. It is of the low kind, such as is termed *asthenic*: in plain words, it is a weakness of the kidneys. "The first circumstance that attracted my notice," says Dr. Prout, *op. cit.*, "after the prevalence of Asiatic cholera, was the disappearance of these (the common lateritious) sediments from the urine. The absence of these sediments was at first considered to be accidental; but when, day after day, the same occurrence took place, I was induced to inquire attentively into the circumstance, with the view, if possible, of ascertaining the reason. On closer inspection, it was found that the urine of every individual examined, whether in apparent health or otherwise, not only presented the same absence of sediment, but also assumed that peculiar appearance, which I had been accustomed to consider as characteristic of the presence of oxalic acid. I likewise noticed," he continues, "an unusually acid state of the saliva, and of the cutaneous exhalations, such as I had never, indeed, before noticed, except in the last stages of chronic diseases, or in malarious affections."

Nothing can be more correct than these remarks. I should like to learn whether the experience of others, who have paid attention to renal disorders, agrees with mine on the present occasion; which is, that the present renal diathesis is more phosphatic than oxalic? What Dr. Prout says in respect of the condition of the urine being that of

malarious affections, is very just. In agueish districts, the urine of most persons is disposed to be pale, copious, and of a low specific gravity; and the absence of the lateritious sediments is so well known, that their reappearance is hailed as a good sign, and looked upon as a criterion of the ague fits having come to their end. This again is another striking analogy subsisting between ague and cholera.

"THE CHOLERA. (FROM THE BOARD OF HEALTH.)

NEWCASTLE, Sept. 22.

Deaths.	{ Cholera	-	-	-	-	59
	{ Diarrhoea	-	-	-	-	1

"Thus, the total number of deaths from cholera and diarrhoea in Newcastle during the present outbreak has been 995.

"In the same period (*viz.* the first twenty-two days) during the prevalence of epidemic cholera there in 1831-2, the number of deaths was 161.

"NEWCASTLE, Friday Morning.

"The weather is still most favourable, and our people are becoming more reassured. The deaths yesterday were *sixty*. In Gateshead only eight. Our local papers this morning give a fearful middle-class obituary. The *Chronicle* has above three-fourths of a column of deaths in Newcastle, nearly all middle-class people. We have had the cholera among us three weeks and one day, and the deaths have been, in Newcastle and the Gateshead Union, the appalling number of 1,318. The following are the statistics of the progress of the disease in Newcastle, made up from the registrar's returns:—

			Cholera.	Diarrhoea.	Total
" August 31 to Sept. 15	-	-	295	20	315
September 16	-	-	101	4	105

"We have lost two medical men, Mr. Irons, surgeon, and Dr. Malcolm, the former gentleman falling a martyr to his duty as a union surgeon. The vicar, the Rev. C. Moody, has opened kitchens for the distribution of beef-tea and boiled rice, in the parishes of St. Nicholas, St. John, and All Saints. They are open to persons of all classes and denominations; and the benevolent throughout the country would serve the cause of humanity and the poor by sending subscriptions to the reverend gentleman. The Omnifance tents will be opened on the moor to-day for such of the poor as are inclined to leave the infected districts. There is also a house of refuge on the New-road. ~~100~~ deaths have occurred in the ~~moor~~ in ~~fact~~ ~~no~~ ~~more~~ ~~than~~ ~~the~~ ~~town~~ has escaped. The epidemic has been ~~and~~ ~~the~~ ~~condition~~ of that town is ~~unwholesome~~.

situation is the garden of the north of England. Before the appearance of the cholera, there was a stout fight for the Public Health Act, and the obstructives were beaten. Some of the medical men opposed the introduction of the act. Mr. Fairbridge, surgeon, has died at Hexham. There are thirteen deaths in that town. The cholera has visited nearly all the villages by the side of the Tyne. There have been four deaths at Howdon and Willington; four at Walker; two at Carville; and several at the Felling. A very interesting and reassuring fact was related to me this morning by a gentleman from Jarrow, a considerable manufacturing village by the side of the Tyne. An old woman who had been to Newcastle and got rather tipsy, on reaching the village ate some half-cooked herring, was attacked, and died after a short illness. Her husband died a few days after. A board of health was immediately formed, under the presidency of the resident clergyman, a "house to house" visitation was instituted, nuisances were removed, etc.; and though there have been between two and three hundred cases of diarrhoea (promptly attended to by the medical officers), there has not been a single death, except those of the two old persons mentioned.

"The epidemic has been very fatal in a village named Whorlton, near Morpeth. Morpeth seems to have escaped." (From the *Times*.)

Brighton, October 1853.

CASE OF POISONING BY CREASOTE; WITH REMARKS.

By J. D. JEFFERY, Esq., Surgeon.

CASE. August 29, 1853, I was called up in the night to see Mrs. B., her husband informing me that "she was in a very strange way, and he thought she was dying."

I found a young woman about twenty-four years of age, in bed. She was insensible; her countenance very pale; frothing at the mouth; pupil quite dilated; pulse regular, rather full, about 80; the circulation seemed undisturbed. Every few minutes there was violent urging, nothing but saliva resulting. The stomach had been emptied by vomiting before I came. She had apparently severe paroxysms of pain on the right side of the face, to which she violently applied her hand; then again became prostrate. Her breath smelt strongly of creasote. A molar tooth on the right side of the lower jaw had a large cavity in it.

I endeavoured to rouse her by washing the face and temples with cold vinegar and water; and, as the paroxysms of pain seemed referrible to the diseased tooth, I fetched an instrument and removed it. She seemed scarcely to feel the operation; but the pain, after a short time, appeared to have left her. In the course of an hour she improved, and became partially sensible.

I administered nothing but a mixture of sesquicarbonate of soda and water. The next morning I found her better, but pale and weak; the pupils of the eyes were still much dilated, and vision was imperfect, which continued for several days.

The patient's own account of the matter and of her sensations, which I took down on her recovery, perhaps may not be uninteresting:—

"Whilst in the act of putting a piece of lint saturated with creasote into my tooth, it slipped, and I accidentally swallowed it. In a few minutes (much less than a quarter of an hour), I felt myself going very low. My eyesight went from me; giddiness came on; and everything looked of a dark blue, even the candles, my husband, and everything. I felt a dreadful burning at my chest. I wanted water to quench the burning at my lungs. I vomited, and brought up the piece of lint with some food. I had great pain at the front of my head, and felt numbed all over. The pain at my chest continued, and my eyesight was imperfect for three or four days. I did not see plain until Friday (Sept. 2nd). I did not know my tooth had been taken out."

I think it right to place this case on record. I am not acquainted with a similar one. I should think there could not have been more than five or six drops of creasote on the lint.

I mentioned this case to Dr. Cormack soon after its occurrence, when he observed that the case was remarkable from the characteristic effects of poisoning by creasote having been produced by a dose not much larger than he was in the habit of prescribing with great advantage in cases of choleraic serous purging. I find upon referring to Dr. Cormack's account of experiments which he performed on animals in 1836, with creasote, the following remarks by that gentleman:—

"From all these experiments, the poisonous effects of creasote appear to bear a very striking resemblance to those of prussic acid. Like the latter, creasote acts toxicologically, either by stopping the heart, or by directly affecting the brain alone—just as the dose may be larger or smaller, or according to the manner in which the substances are introduced into the system. Another very striking point of resemblance between prussic acid and creasote, is the remarkable and almost specific power which they both possess of arresting vomiting, especially if it be unconnected with organic disease." (*Cormack on Creasote*, p. 79.)

In another part of the same work, Dr. Cormack remarks: "In medicine, creasote may be used with great advantage as a sedative or anodyne. To produce such effects, it is given in diseases of the heart, pulmonary complaints, vomiting, and to allay the pain of cancer, etc. A patient under Dr. Shortt, in the Royal Infirmary of Edinburgh, afflicted with cancer of the stomach, derived relief from pain in ten minutes after taking a dose of fifteen drops. When its sedative or anodyne action is wished speedily, the object is best attained by inhaling its vapours." (p. 93.)

From the above extracts, and from the fact of my patient not knowing when her tooth was taken out, clear evidence is afforded of the anæsthetic powers of creasote. It may be remarked that chloroform, the popular anæsthetic agent of the day, is, like creasote and prussic acid, one of the most efficient remedies for vomiting: and that the medicinal as well as the poisonous effects of these three agents possess many striking resemblances.

Lowesmore House, Worcester, Oct. 17, 1853.

ANOTHER SINGULAR CASE OF ALOPECIA.

By GEORGE SELWYN MORRIS, Esq.

It may be interesting to Dr. Barclay's readers in the last number of the *ASSOCIATION JOURNAL* (p. 902), to hear of another singular instance of complete alopecia; and as I have a case of precisely the same nature, I subjoin the following notes.

S. A. W. is a young woman aged 20, residing in this place. Her parents, so far as I can discover, were free from syphilis and scrofula, and were in all respects perfectly healthy people. S. A. W. has not a particle of hair on any part of her body. I have examined her all over; and have only been able to find a slight appearance of down on certain parts of her skin. She began to lose her hair, without any assignable cause, when between eight and nine years of age. She tells me that her sister, a child between six and seven years old, is in exactly the same predicament.

I have not yet commenced the treatment; but my present intention is to follow the plan which Dr. Barclay adopted in his case.

Sydenham, Kent, October 17, 1853.

[Another case of complete alopecia reached us as we were going to press. Ed.]

PERISCOPIC REVIEW.

MIDWIFERY AND DISEASES OF WOMEN.

THE INTERNAL SURFACE OF THE UTERUS AFTER DELIVERY.

In the *British and Foreign Medico-Chirurgical Review* for October 1853, we find an original communication by Dr. MATTHEWS DUNCAN, of Edinburgh, on the state of the internal surface of the uterus after delivery.

This surface, the author says, may be divided into three principal parts: 1. The inner surface of the cervix; 2. The site of the insertion of the placenta; 3. The rest of the inner surface of the body of the organ.

The first of these parts is excluded from discussion at present; for the cervix uteri differs so materially from the body, that it may with propriety be described as almost a separate organ; and the researches of M. Stoltz and others show that the cervix does not become developed so as to form part of the cavity of the uterus.

Dr. Duncan alludes to the opinion entertained by obstetricians, that the entire decidua passes away after parturition, leaving the muscular tissue bare, and that a new mucous membrane is formed by an inflammatory process. This view he regards as paradoxical.

He describes the mucous membrane of the cavity of the uterus in early pregnancy as "very highly developed, forming a rich, soft lining to its inner surface, and contributing greatly to the increased thickness of the parietes of the organ at this time. When the walls of the uterus are examined in advanced pregnancy, the thickness of this structure is found to be greatly diminished, even when the whole structures between the chorion and the muscular tissue of the organ—that is, the proper mucous membrane, or decidua vera, and in addition, the decidua reflexa—are included in the measurement. If, in a woman who has died in advanced pregnancy, the membranes are separated from the uterus, the mucous membrane is left adhering to the walls of the womb; only its surface is lacerated and irregular.*

"In parturition a similar process takes place, with this difference, that after the removal or expulsion of the ovum, the uterus is reduced by its contractions to dimensions very small compared to those it had whilst expanded. The result of this contraction, upon the mucous membrane, resembles its effect on the muscular tissue of the organ. In both, the diminution of superficial extent is the result partly of the expulsion of the large mass of blood contained in their very large vessels, but chiefly of the assumption of a greatly increased thickness of wall. After parturition, the mucous membrane of the uterus is rough and irregular on the surface, and covered over with blood and adherent coagula. As the uterus diminishes in size, its thickness increases."

Dr. Duncan describes the appearance of the uterus after delivery in several cases in which he had an opportunity of examining the organ. The result of these examinations shows that "after delivery the muscular fibres of the uterus are not laid bare, but are covered with a mucous membrane, which is undoubtedly the remains of the uterine decidua." The mucous membrane is found thicker at the insertion of the placenta than elsewhere: it is there marked by elevations and depressions, and by the open mouths of the uterine veins.

In the cow, and many other quadrupeds, the foetal portion alone of the placenta is discharged; while the afterbirth of the human female consists of both the foetal and the maternal portion, the latter including a development of the uterine vessels, and the layer of decidua covering them. But even in women, the anatomical imitation of the process which occurs in the cow is possible: William Hunter performed this operation in a fetus of four months.

"The membrane", Dr. Duncan writes with regard to that

* "These facts I have verified by means of several dissections preserved in the late Dr. Campbell's museum. Albinus, in his *Atlas of Anatomical Plates*, describes the same results of a similar dissection. See *Uteri Gravid, Tab. vii.* His words of description are: 'Ovum exentum. Uteri pars interior, mollis, tenera, veluti spongiosa, canosaque: cui ovum molliter adheret, involucro suo membranaceo.' See also W. Hunter, *Anatomical Description of the Gravid Uterus*, ed. 1843. With his admirable accuracy, W. Hunter describes (p. 47) the adhesion of the decidua to the muscular fibres of the uterus as being 'rather stronger than the adhesion between its external (decidua vera) and internal stratum (decidua reflexa), which we may presume is the reason that in labour it so commonly leaves a stratum upon the inside of the uterus.' And he elsewhere makes the general statement, that 'one stratum of the decidua is always left upon the uterus after delivery.' See also J. F. Meckel, *Descriptive Anatomy* (Eng. trans.), vol. ii, p. 596."

which lines the inner surface of the uterus after delivery, "is easily distinguished from the muscular tissue of the uterus by its softness, and by difference of colour in a cross section. It is in some cases so soft that its surface can with facility be almost completely rubbed off or brushed off the subjacent tissue. And if this manipulation be practised upon it, the investigator will assuredly find no difficulty in discovering the fibrous tissue to be bare, like the muscles in an amputated stump. This softness and friability is undoubtedly one of its characters which has given rise to the erroneous opinions of authors; for we frequently find them speaking of removing a soft membranous or flaky structure, in order, as they imagined, to display the real internal surface or the womb. For example, W. Hunter, in describing a dissection of the uterus of a woman who died at the end of the ninth month without being in labour, states that, finding the internal surface of the uterus everywhere covered with a thin stratum of decidua, he rubbed off the tender membrane with a cloth, in order to expose the subjacent muscular structure. But numerous later investigators have not so correctly appreciated, as W. Hunter did, the nature of the structure they removed in a like manner, and which they believed to be effused lymph, false membrane, bloody coagula, or patches of decidua having no necessary existence there, and ready to be discharged or rubbed off in order to expose the muscular fibres, which they erroneously believed came to be exposed after parturition. We thus find that here, as elsewhere, W. Hunter's accounts of his dissections are still in our day true in almost every particular. But whilst there can be no doubt of the truth of W. Hunter's anatomical description of this part, exception may very justly be taken to the opinion he expresses as to this residuary decidua. He states his belief that 'most of it dissolves, and comes away with the lochia.' Now there is every probability that this takes place in a very different way. The residuary decidua forms the mucous lining of the uterus, and may pass away from the uterus, not in mass, but in the regular insensible exfoliation of such structures, or be removed by the vessels in its substance in the ordinary course of nutrition and absorption. Moreover, when we inquire into the real nature of the discharges from the uterus after delivery, we shall find that they are of a nature and character quite antagonistic to the notions entertained as to the denudation of the muscular fibres, and the formation of a new mucous membrane after the deposition of a false membrane over the supposed wound, and under the influence of an inflammatory process."

The lochia in the healthy female have no resemblance to purulent discharge. They have been frequently and correctly described as presenting three different conditions, in correspondence with as many stages—*lochia cruenta*, *lochia serosa*, and *lochia alba, vel mucosa, vel lactea*: the last is sometimes also called *pyrulenta*; but this is more from theoretical notions than from any resemblance to purulent discharge. Pus sometimes may be observed in the lochia as a result of local inflammation, or from healing lacerations: but it is not a constituent of healthy lochia; it does not appear in them under the microscope; and, when present, it is readily discovered by its characters.

Dr. Duncan then goes on to criticise the custom, general in late years, of "comparing the internal surface of the body of the uterus after delivery to a great wound, or solution of continuity." This analogy originated in modern times with Van Swieten; who, however, seems to have not gone nearly so far as some of his followers. He "points out that after the separation of the chorion and placenta, the inside of the uterus is left covered with the remains of the *tunica cellulosa*, or *substantia cellulosa*, which separates the chorion from the proper tissue of the uterus. He does not describe the uterine muscular fibres as being laid bare, but states that, in addition to the rupture of numerous large vessels, there is—in his own words—*soluta cohesio, recens, cruenta, partis mollis; id est vulnus*; and then he goes on to point out the particulars in which this solution of continuity differs from an ordinary wound. In a subsequent paragraph he states his belief that the fever commonly called *febris lactea* does not arise from the afflux of milk to the mammae, so much as from the superficial suppuration which he describes as taking place on the internal uterine surfaces."

M. Cruveilhier has been most explicit in asserting the denudation of the muscular structure of the uterus: and his words are quoted with approval by Drs. Fergusson, Rigby, and many others. Dr. Duncan points out that John Hunter, Cruveilhier, and others, have fallen into error in assuming the occurrence of inflammation during the natural processes of pregnancy and parturition.

To M. Cruveilhier's assertion that the "muscular structure

the uterus are everywhere exposed" after delivery, the dissections described by himself, Fergusson, and others, form a marked contradiction; for there is found and mentioned an inner membrane of the uterus covering its muscular fibres.

"Finally", Dr. Duncan writes, "did there exist after every delivery a wound of the enormous dimensions of the internal surface of the uterus—dimensions not inferior to those of the wound produced in amputation of the thigh, it is difficult to conceive how parturient females should escape the frightful mortality succeeding that operation, or the like. It would be difficult or impossible to explain why, instead of one in every three or four dying as after amputation of the thigh, there should be only one in every two or three hundred. It can scarcely be asserted that the shock produced, and the circumstances of the supposed uterine wound, are a whit more favourable to recovery in the obstetric than in the surgical patient. The explanation lies in the fact that the chief analogy of the internal uterine surface after delivery, is not with a stump, so far as it consists of incised and denuded tissues, but only in both surfaces presenting numerous open veins liable to become inflamed, or to absorb the obnoxious materials which may be brought into contact with them. And it is to this anatomical circumstance that are traceable most of the cases of death in childbed."

FÆTUS IN UTERO SUPPOSED TO BE KILLED BY LIGHTNING.

Dr. CARITHERS, of Hendricksville, relates a case in a medical periodical of the United States (*Southern Med. and Surg. Journal*), in which he avers that a fetus *in utero* was killed by lightning. He states that Mrs. F., aged about 40, in good health, and eight months advanced in pregnancy, received on the 10th of June, 1852, a severe shock from a streak of lightning, from which she recovered in a few hours, when she was attacked with labour pains. On the doctor's arrival, he found her suffering with sharp pains. On examination, *per vaginam*, no dilation of the os uteri had taken place. He bled her freely, and ordered her an enema of a gill of starch, with a teaspoonful of laudanum, and to take a quarter of a grain of sulphate of morphia every half hour, until she was relieved from pain. After taking the fourth dose the pain subsided. He ordered her to take on the following morning an ounce of castor oil. At two P.M., it had acted freely, and at four P.M., she was resting well. She was delivered on the tenth day after she complained of being very unwell. The child was dead, and from its appearance had been so from the time the mother felt the shock.

ARREST OF DEVELOPMENT IN ONE FOOT ASCRIBED BY THE MOTHER TO A FRIGHT.

The following case is reported (in the *American Journal of Medical Science* of April), by Dr. STORRER of Boston. A lady, three or four months after her marriage, was much affected at seeing a hen injured by a stone thrown by a boy. The stone broke one of the hen's legs, and injured its lower portion. She continually dwelt upon the subject, insisting that her child, when born, would be deformed. In due course she was confined; and it was found that one foot of the child presented evidence of arrested development. The child, perfectly well formed in other respects, exhibited upon one of the lower extremities simply a heel, and the rudiments of the five toes, at the extremities of which were placed minute nails. Dr. Storrer said to the Medical Society of Boston that the striking points in this case were, that the woman had dwelt during the whole time which intervened between the scene with the hen and her delivery upon the certainty of her child being deformed, and that upon its birth she had insisted upon minutely examining it. We really do not see anything remarkable in all this: for women are constantly fancying that they are to give birth to monsters, and also insisting on minutely inspecting what is born, when there is no blemish of any kind discoverable upon their offspring. The case of Dr. Storrer and many others related by those who heard it read, and which with his were attributed to the mental influence of the mother upon the fetus, are certainly, from the vastness of every day negative evidence, rendered of small scientific value as evidence in favour of the theory of mental influence. A long discussion on Dr. Storrer's case was therefore very appropriately closed by Dr. Gould mentioning a "set-off" case. He said that "on last Monday he had attended a woman, who, at the birth of her child was very anxious that its palate should be examined, she having early in her pregnancy seen a person with very disagreeable countenance from deformity of the palate. She had been very unpleasantly affected by the sight: but notwithstanding her very strong apprehension, no effects were visible on the child."

INABILITY TO SWALLOW IN AN INFANT.

In the *American Journal of Medical Science* for July 1853, Dr. J. L. PIERCE, of Bucks county, Pennsylvania, describes the following case.

On the 18th of December, 1839, he was sent for to Mrs. James, in labour of her eighth child. At 11 A.M. she was delivered of a fine large infant, weighing ten pounds. He discovered at birth a tumour on the right epigastrium, extending about a quarter of an inch to the left side of the ensiform cartilage, and its upper edge just below the cartilage of the ribs. It was about one and a half inches in diameter, and nearly circular. No other extraordinary appearance was noticed. On visiting the patient next morning, Dr. Pierce was informed that the child had not taken the breast; and on the succeeding morning the same observation was repeated, with the addition that he did not swallow. The tumour had the same appearance as at first: it was evidently not connected with the internal parts, and was taken for a wen. The child moaned constantly, which the mother stated had succeeded to an incessant crying. There was a constant frothing at the mouth; which Dr. Pierce regarded as produced by the saliva which ought to have been swallowed. With a teaspoon, attempts were in vain made to cause him to swallow some water. On the afternoon of the third day, Professor Hodge saw the child in consultation with Dr. Pierce. He regarded the inability to swallow as connected with the nervous system; founding his opinion chiefly upon a fullness of the brain at the anterior fontanelle. The treatment resolved on was to clear out the bowels with warm water enemata; and then to administer lamb broth injections every three or four hours. After the second warm water injection the child was applied to the breast, and was found able to swallow. It took the breast freely, and experienced no further inconvenience.

CONGENITAL DISPLACEMENT OF THE HEAD OF THE FEMUR ON BOTH SIDES.

In the *Monthly Journal of Medical Science* for May 1853, it is stated that Dr. MERCER ADAMS exhibited to the Physiological Society of Edinburgh, a dissection displaying congenital displacement of the head of the femur on both sides. The head of the femur was displaced from a well-formed cotyloid cavity, and lay on the dorsum of the ilium, where it had formed for itself a new cartilaginous acetabulum. The muscles of the thigh and gluteal region were very much atrophied and contracted. Owing to the contraction of the rectus femoris, the patella and head of the tibia were drawn up over the condyles of the femur, and the knee-joint in consequence could not be flexed. The axis of the neck of the femur was abnormal, being placed nearly horizontally in relation to the shaft of the bone, instead of its natural oblique diameter. The ligamentum teres was elongated, thicker and stronger than is usual in fetal life. This seemed to confirm the view that its function is purely suspensory, and evidenced in a remarkable manner the provision made by nature to counterbalance the malformation; for had this child lived, the whole weight of the body must necessarily have been supported by this ligament, which was formed of unusual strength for this end. From the immobility of the knee-joint, the fetus had been unable to assume its normal ovoid form while *in utero*, and accordingly a false joint had been formed in the lumbar region of the vertebral column, to enable the child to adapt itself to the cavity of the uterus. Mr. Adams considered that the displacement had been caused by the abnormal retraction exercised on the head of the bone by the contracted condition of the muscles attached to it. The position of the fetus *in utero*, as it lies with the legs flexed on the abdomen, was of all others the position which would predispose the head of the femur to slip out of the acetabulum, and to mount upwards and backwards, as in this case, on the dorsum of the ilium.

PRACTICE OF MEDICINE AND PATHOLOGY.

THE EXTERNAL USE OF OIL IN THE TREATMENT OF SCROFULA AND PHTHISIS.

Dr. SIMPSON, of Edinburgh, has elaborately shown in the *Monthly Journal of Medical Science* for October 1853, that the popular belief that the greasy workers in cloth factories are a healthy class, and remarkably exempt from scrofulous disease, is well founded on many facts. We do not know of any treatment more useful for puny scrofulous children than a thorough nightly inunction after a tepid bath. The system never disagrees, and is compatible with the internal use of cod-liver oil, iodide of iron, or any other suitable medicine. The inunction never disagrees; but from its soiling the linen, it is not easy to get mothers and nurses to carry it out.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

SATURDAY, OCTOBER 15TH, 1853.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.

PARACENTESIS IN AN INFANT. BY J. M. WINN, M.D.

Dr. WINN related the case of an infant nine weeks old, in whom he had performed paracentesis abdominis on account of ascites. At the first operation, he removed a quart of milky fluid; at the second, he drew off rather less. On this occasion, oozing of blood occurred from the wound of a small vessel, and the child died. On *post mortem* examination, the liver was found diseased, probably congenitally. Dr. Winn believed this was the first time the operation had been performed in so young a subject.

PYROLIGNEOUS OIL OF JUNIPER. BY C. H. F. ROUTH, M.D.

Dr. ROUTH exhibited a specimen of the pyroligneous oil of juniper, or juniper-tar soap—a preparation in extensive use in Germany. He had found it very successful in the treatment of eczema rubrum.

IMPERFORATE ANUS. BY HENRY SMITH, ESQ.

Mr. H. SMITH exhibited the rectum and bladder of an infant, who died with imperforate anus. A communication existed between the bladder and the distended *cul-de-sac* of the rectum.

SUPPURATION OF THE JOINTS FROM INFECTION OF THE BLOOD.

BY WILLIAM COULSON, ESQ.

After referring to the obscurity which has commonly prevailed among writers with regard to the suppurative affection of the joints following puerperal fever, amputations, operations on the genito-urinary organs, etc., and having described some illustrative cases, Mr. COULSON observed that the origin, course, symptoms, and morbid anatomy of this articular disease are of a peculiar kind, and such as altogether to contradict the supposition of its being of a merely local character. The main features of the disease are always the same; any symptoms which would appear to indicate a variety of origin being accidental. The joints affected during life are found to contain more or less pus, but not in evident relation to the intensity or duration of the local complaint. The synovial membrane generally presents traces, though slight, of recent inflammation; and in some cases it has been found free from vascularity. Mr. Coulson did not regard this as a proof of the non-inflammatory nature of the disease, but considered that the injection of the vessels had disappeared after the secretion of pus. The cartilages and other articular tissues are usually healthy; but, in many cases, the cartilages are more or less eroded or absorbed; and, in a very few cases, the bone has been affected. The tissues round the joints are often the seat of sero-purulent infiltration or circumscribed abscesses, which are also found in the muscles of the limb.

Suppurative disease of the joints in puerperal females has been confounded with puerperal fever; but, according to Mr. Coulson, puerperal women are often attacked by purulent disease of the joints without any of the symptoms of puerperal fever; while puerperal fever may be complicated with purulent inflammation of the veins, in which cases there may be secondary articular disease. That purulent inflammation of the joints does not essentially depend on puerperal fever, is shown by its occurrence in certain cases of abortion in the early months of pregnancy.

The author then insisted on the necessity of not confining attention, in the *post mortem* examination, to the joints, but examining other parts of the body. Pus is almost always found in some one or more of the internal organs.

The symptoms of the disease were then examined, under the head of shivering, fever, and affection of the respiratory organs, and those connected with the seat of the original injury. Having described the symptoms of an uncomplicated attack in puerperal females, Mr. Coulson observed that the disease is much more fatal in such subjects than in males, probably from its being frequently complicated in females with puerperal fever.

The author believed the contamination of the blood to arise from admixture of pus. He referred to the occurrence of suppurative disease of the eye in puerperal females—an affection not understood until it was shown that it occurs in other cases of purulent infection.

Those cases in which purulent disease of the joints has occurred in puerperal fever without apparent morbid alteration in

the uterine veins, do not, according to the author, negative the theory of purulent infection; for inflammation of the mammary veins or of the rectum is capable of exciting purulent infection.

The paper concluded with some remarks on the treatment, which should be directed towards counteracting the poisonous condition of the blood.

An interesting discussion ensued, in which Drs. Copland, Winn, James Bird, and Hare, and Messrs. Harrison and Henry Lee, took part; but which, from the great demands on our space this week, we are compelled to omit.

EAST SURREY CHOLERA SOCIETY.

TUESDAY, OCTOBER 18, 1853.

ROBERT WILLIS, M.D., in the Chair.

The first meeting of the East Surrey Cholera Society was held at Richmond, on Tuesday evening, Oct. 18th. Dr. WILLIS, of Barnes, was called to the chair.

THE CHAIRMAN read the following circular calling the meeting:—

"MY DEAR SIR,—I am requested to inform you that, at a meeting of the Provisional Committee of the East Surrey Cholera Society, held to-day at the Reading Room in Mortlake, it was moved by Dr. CORMACK of Putney, seconded by Mr. PALMER of Mortlake, and unanimously agreed—

'That all qualified members of the medical profession residing in East Surrey should be invited to meet at W. Ethrington's Music Hall, Hill Street, Richmond, on Monday, the 18th of October, at seven o'clock p.m. precisely, for the purpose of constituting and organising the above-named society.'

"Your presence on this occasion is earnestly desired; and if that is impossible, you will oblige by communicating, in a letter to me, for the information of the meeting, your opinion in reference to this movement. I have the honour to be, sir,

Yours faithfully,

"BENJAMIN W. RICHARDSON.

"Hon. Sec. to Provisional Committee.

"Mortlake, October 11th, 1853."

Dr. Willis read letters from the following gentlemen, who had been invited to attend as visitors: Dr. Babington; Thomas Hunt, Esq.; Dr. Gavin Milroy; Dr. E. C. Seaton; Dr. Snow; Spencer Wells, Esq.; and Dr. J. A. Wilson. We insert the letters of Drs. Babington, Milroy, and Snow.

"31 George Street, Hanover Square, October 16th, 1853.

"MY DEAR SIR,—I feel much honoured by your invitation to the meeting of the Provisional Committee of the East Surrey Cholera Society, to be held at Richmond, on Tuesday evening, the 18th instant. Fully approving as I do of the object implied in the name of the society in question, and highly respecting as I do the gentlemen of the Provisional Committee, and their Honorary Secretary, it would have been to me very gratifying to be present on the occasion of the formation of this society. Unfortunately, however, on the evening of the 18th, the Pathological Society of London holds its first meeting for the season; and, as I have the honour to be its President, I cannot with propriety absent myself on the occasion.

"As President of the Epidemiological Society, I venture to express a hope that your society and ours may be able mutually to assist each other. I am quite sure I may say for ourselves, that we shall be most willing to co-operate with you.

"I have the honour to be, my dear sir, yours very truly,

"To B. W. RICHARDSON, Esq."

"B. G. BABINGTON.

30, Fitzroy Square, 17th October 1853.

"MY DEAR SIR,—It would give me much pleasure to be present at the intended meeting to-morrow evening at Richmond; but I much fear that it will be quite out of my power to be so, in consequence of business which will detain me in town until very late in the afternoon. There can be but one opinion, I should suppose, as to the extreme usefulness of local associations devoting themselves to the investigation of cholera in their own immediate districts more especially. It is an epidemic whose history is alike so remarkable and so instructive, that it well deserves our studious attention in every point of view, scientific and practical.

"As Chairman of the Cholera Committee of the Epidemiological Society, I may mention that we have been busily engaged for some time past in drawing up a series of queries, which we hope to be able to issue very soon to the medical profession, not only in this country, but also abroad, with the

view of obtaining accurate data from various parts of the world. It will give me much pleasure to forward a copy to you as soon as they are printed. Let me also say that if there are any documents issued by the General Board of Health which the East Surrey Society may wish to be provided with, I shall be happy to endeavour to procure them for the use of the members.

"I remain, dear sir, very truly yours,

"B. W. RICHARDSON, Esq."

"G. MILROY.

"18 Sackville Street, October 17th, 1853.

"MY DEAR SIR,—I feel much honoured by the invitation to attend the meeting of the Provisional Committee of the East Surrey Cholera Society, to be held to-morrow evening; and I regret very much that I shall not be able to be present to witness the organising of the society.

"I am very much pleased to hear of the formation of your society. I feel sure that much valuable experience of the two former epidemics of cholera has remained in a great measure useless, for want of some means by which it might have been collected and made generally known to the profession.

"Should the epidemic with which we are threatened unfortunately occur, the united efforts of the medical men residing in a district not so densely populated as a large town, nor yet so widely extended as to prevent their meeting together occasionally in a society, may be reasonably expected to furnish a more important contribution to the history of the disease than any which has yet appeared.

"I remain yours very truly,

"B. W. RICHARDSON, Esq."

"JOHN SNOW.

After making a few remarks upon the origin of the Society, the Chairman stated Mr. Richardson had been requested by the Provisional Committee to prepare a paper explaining the objects of the Society, which he (the Chairman) would now call for.

Mr. RICHARDSON then read the following address:—

GENTLEMEN,—You have heard from the Chairman that the Provisional Committee of the Society we have now met to organise, has requested of me to draw up a report or address, explanatory of the objects, the value, and the constitution of the proposed Society.

Let me enter upon the point at once. There is at this moment in the land a fearful disease, the causes of which are utterly unknown, and concerning the treatment of which the wisest amongst us are almost as little informed as are the poorest and most uneducated of our fellow men.

It is known also to all of us, that in the two previous epidemics of the disease, the untiring and noble labours of the medical profession met with but little success or reward; that professional men themselves felt and still feel distrust in their efforts to understand and meet the disease; and that the knowledge of the profession in this case does not stand so high above the knowledge of the people as is requisite for securing to our body that degree of veneration and confidence, which we honestly claim, and should in honesty receive.

In tracing out the causes of our failures it has occurred to many, and it may be to everyone, that at least one cause of failure lies in the fact that as yet the disease in question has only been observed in its isolated character, that no great and general observations have been made upon it, and that it has ever been seen and described by man the individual, never by man the universal.

There are some grand phenomena in nature which are always present, such as the rolling of a planet; and there are others which are fleeting, such as the advent of an epidemic. If we would unravel the mysteries of these phenomena, we must do so by the agency of a multitude of minds. The process of observation is, however, different in each case. In the investigation of the permanent phenomenon, time is allowed; and one single individual in one age may work usefully and progressively, since he may start on the last footmark of him who preceded, and may have the problem for solution always before him. In the investigation of the fleeting phenomenon, the single individual is a nullity: and the difficulty of discovering its nature can only be overcome by bringing the whole competent mental strength of the time to bear upon it.

To attempt in a small way what might indeed be attempted in a much larger way, to form, in a few square miles of the earth's surface, a nucleus of concentrated observation, that might in the end, and with more ease than some other things, be extended to the whole earth, is the first and the most important object contemplated in the present movement.

There is of course no plan or thought of the Provisional Committee which is not open to amendment, modification, or re-

moval, by this meeting. With this remark, I may venture to explain freely the intentions of the committee. These are—

1. To establish in the district called East Surrey, the parliamentary division being understood, a society, to be named the East Surrey Society for the Observation of Cholera. The society to consist of a President, Vice-Presidents, Secretary or Secretaries, a Treasurer, Councillors, Honorary Members, and Members.

2. To have monthly meetings of this society, held at various towns in the district, so selected as to suit the convenience of all members.

3. To originate and encourage the formation of local committees of the society, which should meet weekly during the period of the epidemic, and frame brief reports of all the cases of cholera that have occurred in their special localities.

4. To arrange that, at the general meetings of the society, these local reports should be read and received, and that at each meeting some particular point connected with cholera should be set apart for discussion; a committee selected from the members of the whole society having been previously appointed to prepare a report on the subject to be discussed. The report to be read previous to the discussion.

5. To make provision that the Council of the Society, after each general meeting, shall prepare a full report of all the labours of the society since the previous meeting. These reports to be printed in one or more of the medical periodicals.

6. To fix on a small subscription to be paid by each member, to defray the expenses incurred by correspondence and other matters.

These, gentlemen, are the propositions submitted to you by the members of the Provisional Committee. One or two other matters, of a general and suggestive character, deserve attention.

It is proper especially to point out the necessity of making this society mutually honourable to its members, and of taking care that the utmost liberality should enter into the spirit of its laws.

In answer to some gentlemen, who have objected to join the society because they may be unable to attend its meetings, I would respectfully but earnestly observe, that, although the meetings of the society will be an interesting and essential part of its proceedings, the non-attendance of a member at these meetings will by no means prevent him from being an useful and indeed a necessary member of the society: inasmuch as each one may send to the nearest local committee, or to the Council of the Society, particulars of all the cases of cholera that have occurred under his observation, and may thus supply that information which it will be the chief object of the society to collect and digest.

An idea has been expressed by a few persons, that the cholera seems to be on the decline, and that this society is therefore unrequired. But were this opinion really correct (which is not the case), there is no reason why this movement should be suspended; for the society, being once formed, could remain, ready at any moment to commence or resume its labours; while in no instance is the value of the old proverb, "Seize time by the forelock," so applicable as it is in reference to the investigation of cholera.

Again, if positive action is necessary for the life of the society,—and it is possible that such is the fact,—then I would point out that there is ample scope for the development of that action in the absence of the alarming plague now in our homes. There are many other epidemic diseases, which, in their familiar and constant manner, bring more death and misery into this world than this cholera, which does but attract our particular attention because it wakes like a demon, and after doing a day of demoniac work, sinks again into such profound quiet, that its breathing can scarcely be heard. These other diseases, the society under a modified name might, with great advantage, make the subject of special observation.

The matters which ought at this moment to receive the attention of the society now proposed, have reference only to cholera: and first, the treatment of the disorder should claim immediate regard. There is something so monstrously extravagant in all our doings in this matter, up to the present time, that it is no wonder the world should sneer at our incompetency. The proverb *quot homines, tot sententiae*, might, in reference to the treatment of cholera, be most appropriately turned into *quot medici, tot remedia*. Nor can we hope to escape from such censure while every man is jumping up with lo here, and lo there is a remedy. The world knows, and we know that amongst all this wild hubbub there is not one remedy in which absolute confidence can be placed. But if we can unite our intellects, if we can

look at the characters of the disease as though it had nothing to do with life, fix upon some decided plan of action, carry out that plan right heartily, and then pronounce our success honestly, we shall surely save as many lives as if we went individually to work; and, be our results affirmative or negative, we shall certainly have some great facts to show at the end of our labours.

A wide field is opened to our united efforts in the discovery of the causes of cholera; and in this inquiry we may all do something. In the matter of meteorological observation alone, everything admits of being observed. And the man who, on going to bed and on getting up, will put down six letters to indicate the state of the barometer and thermometer, or will watch a bit of paper for indications of ozone, is doing valuable service.

Those gentlemen who have time and taste to pursue the subject in a physiological manner, have likewise ample room for their experimental researches. Indeed, we know now, though many may object to admit the fact, that the practice of medicine in general only progresses in proportion as the physiologist steps forward and rends the veil that conceals from our sight the working of the laws by which we live, move, and have our being.

I beg, moreover, to show that the combination now anticipated, must, if carried out, prove instructive and pleasant to ourselves. It will tend to increase personal acquaintance, to soothe down many of those asperities which arise in the distant conflicts of life, and will afford us all the satisfaction of feeling that when a dreaded pestilence made the face of the world grow pale, we rose in brotherly phalanx, to advise the suffering, support the timid, meet the enemy, and compose a history of our labours for the instruction of those who shall follow us.

If, indeed, the society now contemplated could be carried out as fully as its promoters would wish, I believe that, however severe an epidemic of cholera may visit the East Surrey district, the disease would be so well policed, that when it has passed away, it might be said, Here is a piece of country in which not a single case of cholera has been allowed to occur, without having some part of its history written, preserved, and made use of, in the reports issued by the council of the society. The value of reports made out of such materials, in affording information on the causes, mode of progression, and the treatment of cholera, are too obvious to require comment.

Gentlemen, I have now conveyed to you as clearly as I am able, the motives that induced the committee, of which I am the secretary, to call you together.

It would be out of place, and presumptuous in me, to endeavour by words of my own to stimulate to interesting and great exertions, men so earnest as you all are in every good and useful work. But, should anyone feel doubts as to the possibility of realising the scheme now proposed, I trust I may without offence remind him of the truth bequeathed to us by the world's poet philosopher—

"Our doubts are traitors,
And make us lose the good we oft might win
By fearing to attempt." (Applause.)

Mr. RICHARDSON having been requested to act as Secretary to the meeting, it was moved by Dr. JULIUS of Richmond, seconded by Mr. RAY of Dulwich, and unanimously carried—

"That Mr. Richardson's excellent statement now read be entered on the minutes; and that the gentlemen present do form themselves into a society, under the name of the EAST SURREY CHOLERA SOCIETY, with power to add to their number qualified medical practitioners residing within East Surrey."

After some conversation, it was then agreed that the medical gentlemen residing within the bounds of East Surrey, who had responded approvingly to Mr. Richardson's circular, should be enrolled, along with those present, as original members of the society.

It was moved by Mr. GROVE of Wandsworth, seconded, and unanimously carried:

"That the society consist of honorary and ordinary members; and that the Council consist of a President, six Vice-Presidents, a Treasurer, a Secretary, and six other members."

It was moved by Dr. GRANT of Richmond, and seconded by Mr. PALMER of Mortlake:

"That Dr. Willis of Barnes be requested to accept of the office of President for the next twelve months."

Dr. WILLIS said that, for every reason, including seniority, he would rather see Dr. Grant himself in the chair; but, upon Dr. GRANT stating that he contemplated being from home for some time at an early period, and that he could not therefore with propriety accept an office which ought to be one of activity and diligence, Dr. Willis agreed to accept the proffered honour. The motion was then put, and carried unanimously.

It was moved, seconded, and unanimously agreed:

"That the following gentlemen be requested to accept of the office of Vice-President for the next twelve months:—Dr. Cormack of Putney, Dr. Cox of Kingston-on-Thames, Mr. Bottomley of Croydon, Dr. Grant of Richmond, Mr. Grove of Wandsworth, and Mr. P. Martin of Reigate."

It was moved, seconded, and unanimously agreed:

"That the following gentlemen be requested to act as Members of Council for the next twelve months:—Mr. Chapman of Richmond, Mr. Fennell of Wimbledon, Mr. Palmer of Mortlake, Dr. Paul of Putney; Mr. Ray of Dulwich, and Mr. Shillito of Putney."

It was moved, seconded, and unanimously agreed:

"That Mr. James Smith of Richmond be requested to act as Treasurer, and Mr. B. W. Richardson of Mortlake as Secretary, to the society."

In moving the above resolution, Dr. CORMACK mentioned that the merit of having originated the idea of a Society for the Observation of Cholera in East Surrey belonged exclusively to Mr. Richardson. To secure that unity and celerity of action which were of the utmost importance, and from the want of which so many societies failed, he urged upon the meeting the advantages of the society having only one general secretary; it being understood that, in each locality, members might appoint local secretaries, if necessary.

It was moved, seconded, and unanimously agreed:

"That the Council be requested to prepare a draught code of laws, to be submitted to the next meeting of the society."

Dr. CORMACK moved the two following resolutions:—

"That the Council be instructed to prepare a report of the proceedings of this meeting to be sent to every qualified practitioner in East Surrey; and to forward along with this report a series of queries, and printed schedules for the record of observations on cholera, choleraic diarrhoea, and the prevailing character of all diseases.

"That the Council be requested to prepare with the least possible delay a report upon the treatment of cholera, to be read and discussed at the next meeting of the Society."

He (Dr. C.) considered that the resolutions which he had moved in accordance with the wishes of the provisional committee, demanded attention as well as approval. It was, he thought, most important for the Society not to lie dormant till the pestilence was rife. There was at this time already good work waiting to be done by observing the peculiar character which was impressed on all diseases. Again, the cases of serous diarrhoea so abundant (and of which he had had several within the last few days), were well deserving of the most careful study: for what were the cramps and collapse of cholera but the secondary results of a loss of the serum of the blood? As regarded the second of the two resolutions which he had proposed, it might be said that it was reversing the right order of things for the Society first to discuss the *treatment*; but he did not think so. There was undoubtedly much known on this subject. That knowledge, however, was not widely diffused; and was sadly overlaid by empirical writings of the most worthless description. It was, therefore, he thought, for the sake of humanity, the first duty of the Society to direct its attention to the subject of treatment; and he thought that there were abundant materials for a most instructive report and discussion upon that subject.

Dr. GRANT, of Richmond, seconded the resolutions. At a future meeting of the Society he would express his peculiar views regarding cholera; but at present he would wish to urge attention to the recent leading articles in the ASSOCIATION JOURNAL upon medical meteorology, from the study of which science as promoted by that JOURNAL, and as now being widely cultivated, he anticipated great results. He thought that it would soon be proved that cholera did not spring from an inscrutable morbid agent residing in ditches and drains. Its origin and its mode of extension would be found to obey certain laws connected with meteorological changes, however much other local causes might predispose persons to its influence.

Both resolutions were then put from the Chair and carried unanimously.

The time and place of the next meeting then formed the subject of discussion. It was at last understood that the President should summon the next meeting by circulars, for Tuesday, the 15th November, at Wandsworth, provided the business assigned to the Council could be accomplished by that date.

A vote of thanks was then passed to Dr. James Bird, Dr. Sibson, and Mr. Grainger for their presence: and that there made honorary members of the society.

Mr. GRAINGER returned thanks in a very interesting manner.

He said that the practitioners of East Surrey had that evening most honourably distinguished themselves by the way in which they came forward in the sacred cause of science and of humanity. He then glanced at the value of meteorological observations, and at the importance of noting the quantity of ozone in the atmosphere. It would be well for the society to investigate *reasonable modes of treatment*, by making observations carefully and scrupulously in accordance with the exact recommendations of those by whom the plans were suggested or recommended. The precise stage in which a remedy was used, and every minute particular regarding its employment ought to be noted at the time and on the spot. This was the only way to get useful data: and it was from a society such as had been that night constituted that such information was most likely to be obtained. From a multiplicity of imperfectly observed cases no lessons could be derived. He (Mr. Grainger) was anxious, however, to say that in his opinion it was *preventive medicine* which had been and was destined to be most enriched by the scientific cultivation of epidemiology. This was a field which promised a rich harvest. The East Surrey Cholera Society, and other societies which might be formed upon its model, might, he felt assured, be made powerful instruments of public good. They might issue suitable instructions to the public, and they might beneficially influence public authorities, and even the Government of the country. He might with all confidence reiterate the sentiments of Dr. Babington's letter; and say that it would at all times be a source of pleasure to the members of the Epidemiological Society as individuals, and in their collective capacity, to cooperate with the East Surrey Cholera Society, and to assist them as much as they could in their researches and discussions.

Dr. STANON said that, as a member of the Epidemiological Society, he heartily concurred in Mr. Grainger's expression of fraternity. There was need of cholera societies. In 1832, when studying at Edinburgh, he had been baptised into the profession by taking charge of a cholera hospital. He well remembered the consternation and dismay at the mortality which then prevailed. The disease was then looked upon as an exotic. It came and went, they knew not how. With the pestilence, the panic also passed away. Cholera, however, had returned again and again; in fact, it now dwelt among us. It was no longer an exotic; and it remained to be seen whether it could not be rooted up, as had been the plague.

Dr. JAMES BRID, in an animated address, approved of the objects of the society. The career of action which was before it was a noble one, and, by following it, the medical profession could not fail to be elevated in the public estimation, as the public would be thereby taught that our highest ambition was to prevent disease; and that the old system of mere drugging and dosing was no longer to be tolerated.

The various gentlemen who had been invited to attend as visitors were unanimously elected honorary members of the society. The annual subscription of members was fixed at five shillings. All present contributed this amount, and one or two made additional donations. On the motion of Mr. PALMER, a vote of thanks was passed to Mr. Richardson; and, on the motion of Dr. GRANT, a similar compliment was bestowed on Dr. Willis. The meeting then adjourned, between nine and ten o'clock.

ASSOCIATION INTELLIGENCE.

MEDICO-ETHICAL COMMITTEE.

The MEDICO-ETHICAL COMMITTEE of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION will meet at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Thursday, November 3rd, at 3 P.M. precisely.

W. H. MICHAEL, *Hon. Secretary.*

METROPOLITAN COUNTIES BRANCH:—COMMITTEE ON GRATUITOUS ADVICE.

The Gratuitous Advice Committee of the Metropolitan Counties Branch will meet at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, on Thursday, November 3rd, at 3 P.M. precisely.

THOMAS CHARLES, *Hon. Secretary.*

[We have been requested to state that arrangements have been made by the Secretaries of the above Committees for holding the meetings at the same time and Tavern, in order that, if a conference should be considered necessary, it may be at once obtained. EDITOR.]

EDITOR'S LETTER BOX.

CURE OF STRABISMUS BY PRISMATIC SPECTACLES.

LETTER FROM SPENCER WELLS, ESQ., TO THE EDITOR.

SIR,—In your paper of yesterday, you do me the honour of noticing a paper of mine on the cure of squinting, by the use of prismatic spectacles. As, at the same time, you add one or two remarks which are calculated, I think, to discredit what I am convinced will prove a valuable addition to surgical therapeutics, perhaps you will allow me to offer a few words in explanation.

You state, "We scarcely understand the principle on which such an apparatus is to act in altering the direction of the squinting eye." The principle is very simple. The prism is placed before the squinting eye. The light passing through it is refracted in various degrees, according to the angle of the prism. Accordingly, the rays are thrown on to the retina, and form the picture of any object which is looked at, at a spot which does not correspond with that on which the picture is formed on the opposite eye. Diplopia is the necessary consequence; and to obviate this, involuntary contraction of one of the straight muscles takes place. It is this increased contraction called for from a weakened muscle which explains the curative power of the prismatic glasses.

You also imply that the glasses must be inferior to the old plan of binding up one eye. This is, no doubt, correct in some cases, as in one which I noticed in my paper. But in cases of slight squinting in young persons, where there is no great difference in the power of the two eyes, as tested by reading distance, the glasses are much more rapid in their efforts. Six weeks is about the time required to effect a cure in such cases; while the bandage must be worn from six months to a year. The experience I have had myself, and what I have seen in the practice of Dr. von Gräfe, in Berlin, enables me to recommend the prismatic spectacles very strongly in those cases of slight strabismus in young persons, which, though disfiguring, are not sufficiently so to lead to a ready consent to, or desire for, an operation; and in those cases where, after operation, improvement is attained without a perfectly accurate corresponding position of the two eyes.

I am, etc.,

T. SPENCER WELLS.

30, Brook Street, Grosvenor Square, Oct. 8th, 1853.

ON DIVISION OF THE PORTIO DURA IN TIC.

LETTER FROM CHARLES TAYLOR, ESQ., TO THE EDITOR.

SIR,—In the volume of the *Transactions of the Provincial Medical and Surgical Association*, I find in a monograph by Dr. Morris, "On Neuralgia", a recommendation by that gentleman to divide, in certain cases of tic douloureux, the trunk of the "portio dura" or facial nerve.

As that nerve is one of *motion* and not of *sensation*, I am at a loss to understand what good effect he can expect from such division, and certainly cannot suppose that paralysis of the whole of the muscles of *expression* of one side of the face (the necessary result of the operation) is what he would willingly inflict on a patient merely suffering from facial tic; more especially as the original affection would, in all probability, remain unaltered in intensity. I would humbly suggest in those cases where tic apparently affects the portio dura that it may be owing to neuralgia of ascending branches of the "cervical plexus", or to the anastomoses of branches of the fifth pair with some rami of the facial.

Perhaps Dr. Morris may throw some light on this matter. In the meantime, I can only trust that surgeons will "think twice" ere they entail the results of a paralytic stroke or fit of apoplexy on a patient seeking relief merely from a neuralgic affection.

I am, etc.,

CHARLES TAYLOR.

Ilkeston, Derbyshire, Oct. 9th, 1853.

[Dr. Morris thus describes the operation. Page 34, vol. 10. "Division of the portio dura or facial nerve." "An incision of about one inch and a half in length must be made from behind the ear downwards, anterior to the mastoid process, a little dissection will expose the edge of the parotid gland, and the edge of the mastoid muscle, after a few more incisions between the parotid gland and the mastoid process, the facial nerve will be seen, which must, by means of a probe, be lifted up—and a portion of it cut out!"]

TOPICAL TREATMENT OF HOOPING-COUGH.

LETTER FROM WILLIAM BAYES, M.D., TO THE EDITOR.

SIR,—I have read with equal attention and pleasure the excellent paper "On the Topical Treatment of Hooping-Cough", by Dr. Eben Watson, which appeared in our JOURNAL of the 20th of August.

Dr. Watson complains, and with some show of reason, of the want of consideration which has been shown to his views on the subject. I believe this has arisen from the heroic nature of his proposed treatment. The public opinion will never allow its universal adoption. Children will resist to the utmost rather than allow the introduction of the "probang", and their struggles will render the application, even by a determined man, a matter of very great difficulty and uncertainty.

I should wish to inquire, through the medium of your JOURNAL, whether Dr. Eben Watson has tried the less formidable application of the solution to the soft palate and tonsils?

I have never tried its effects in hooping-cough, having always been satisfied with the effects of alum, combined with the daily use of emetics or aperients; but in cases of catarrhal cough, and in cases of bronchitis, accompanied by profuse expectoration, I have long found the most remarkable effects produced in allaying the cough by the use of a solution of nitrate of silver, varying from eight to twenty grains to the ounce, and applied twice or thrice a day by means of a camel's hair brush. Even in cases of phthisis I have never been disappointed in finding it produce a marked diminution of the strength and frequency of the cough, when steadily persevered in.

It may be objected, that it is contrary to the pathology of these diseases to expect any good effect from topical applications to the fauces or soft palate. I know from experience that it diminishes cough, and thus it removes one of the most frequent causes of congestion and inflammation; for cough, though often the sequel, may also be the cause of these, and always tends to increase them when present.

I am etc., WILLIAM BAYES.

Brighton, September 8th, 1853.

NEWS AND TOPICS OF THE DAY.

ROYAL COLLEGE OF PHYSICIANS:—CHOLERA. The following circular was issued on October 15th, by the Cholera Committee of the College of Physicians:—

"The Cholera Committee of the Royal College of Physicians have received from various quarters applications for some plain directions calculated to be of service to the public during the prevalence of epidemic cholera, when medical advice may not be immediately at hand, and before such advice can possibly be obtained.

"For this reason the committee deem it right to offer to the public some instructions, which, on account of an extended 'Notification' having been issued by the General Board of Health, on the 20th of September 1853, may be brief; and are in no case intended either to supersede the necessity of having recourse, as speedily as possible, to further medical assistance, or to impose any authoritative restriction on medical practitioners.

"During the Prevalence of Cholera:—1. No degree of looseness of the bowels should be neglected for a single hour. Medical advice should be at once sought when the looseness begins; and, previous to the arrival of a medical attendant, some of the medicines, at other times used for checking diarrhoea, should be taken; for example—the chalk mixture; the compound cinnamon powder; or the compound chalk powder with opium, in doses of from 20 to 40 grains for an adult.

"2. No saline aperients or drastic purgatives should be taken without the advice of a medical man.

"3. Intemperance in eating or drinking is highly dangerous. But the moderate use of vegetable as well as animal food may be recommended; and, in general, such a plan of diet as each individual has found by experience to be most conducive to his health; for any considerable change in the diet to which a person has been accustomed is seldom advisable during the prevalence of an epidemic.

"4. Debility, exhaustion, and exposure to damp, render the poor especially subject to the violence of the disease. The committee urge upon the rich the necessity of supplying those in need with food, fuel, and clothing.

"5. The extreme importance of removing or counteracting all impurities, whether in the air, water, or soil, as by ventilation, cleanliness, and the free use of the chloride of lime or chloride of zinc, cannot be too strongly insisted upon.

"Lastly. Since the reports made to the College of Physicians shew, that of the persons who were engaged about the sick in the last epidemic, the number of those who were attacked by the disease was, in proportion, exceedingly small, the fear of infection may be practically disregarded.

"The committee forbear to dwell upon the extreme importance of providing medical attendants at dispensaries for the treatment of diarrhoea among the poor: of organising in every district affected by cholera what is called the system of 'house to house visitation'; and of establishing temporary hospitals for the reception of patients who cannot be properly treated at their own homes; because these measures have been strongly and properly enforced in the 'Notification' published by the General Board of Health."

METHOD OF DETERMINING THE INTENSITY OF LIGHT. The *Athenæum* of October 1st quotes the following remarks from a letter lately received from Berlin:—

"It is well known that the paper prepared for photography, grows more or less black by rays of light falling on it. One of our young painters, M. Schall, has just taken advantage of this property in photographic paper to determine the intensity of the sun's light. After more than 1,500 experiments, M. Schall has succeeded in establishing a scale of all the shades of black which the action of the solar light produces on the photographic paper: so that, by comparing the shade obtained at any given moment on a certain paper with that indicated on the scale, the exact force of the sun's light may be ascertained. Baron Alexander von Humboldt, M. de Littrow, M. Dove, and M. Pongendorff, have congratulated M. Schall on this invention; which will be of the highest utility, not only for scientific labours, but also in many operations of domestic and rural economy."

QUACK DOCTORS THRIVE IN ENGLAND. The census of 1841 showed 21,435 persons practising one or more departments of medicine without qualification. The youth and sex of some of the practitioners was also remarkable. In Birmingham, there was one "herbalist" under 20 years of age; two "keepers of lunatic asylums" under 20: fourteen female "leech-bleeders"; and one female "physician". One female "dentist" in Taunton; a "physician" in Norwich under 20; two "medicine vendors" in the Tower Hamlets under 20; one "midwife" in Preston under 20; one "physician" in Canterbury under 20; and two "physicians" in Bristol under 20.

MARRIED COUPLES IN WORKHOUSES. Information is given in a return to the House of Commons, procured at the instance of Mr. Pellatt, M.P., of the number of married couples, above sixty years of age, living together and separate in workhouses on the 1st of January last. In England the number who were inmates of workhouses, and living together, on the 1st of January, was 298, and in Wales 1, making 299. The number of married couples above sixty, who were inmates of workhouses, and living separate, on the same day, was in England 575, and in Wales 3, making 578. The return does not comprehend the single parishes under the 43d of Elizabeth.

ZOOLOGICAL GARDENS, REGENT'S PARK. The Zoological Society are now exhibiting, for the first time, an adult living example of the great South American anteater (*myrmecophaga jubata*), by far the most remarkable animal which they have acquired since the hippopotamus. The extreme singularity of its form, the marked character of its colouring, and its very considerable size, will, in all probability, render this acquisition as interesting to the public in general, as it cannot fail to be to the scientific world. The great difficulty of transporting an animal whose food has hitherto been supposed to consist entirely of insects from the forests of South America to an artificial home in the Regent's Park has, up to this time, prevented the society from filling up the important desiderata of their series, which they have now had the good fortune to acquire.

[Up to our going to press Dr. Hoskins' Report had not arrived.

NEWS AND TOPICS OF THE DAY.

[Continued from page 936.]

ROYAL MEDICAL AND CHIRURGICAL SOCIETY OF LONDON: 1853-54. Meets at half-past eight o'clock precisely. In 1853: Tuesdays, November 8 and 22; December 13. In 1854: January 10, 24; February 14, 28; March 14, 28; April 11, 25; May 9, 23; June 13, 27. Anniversary Meeting, Wednesday, March 1, at four precisely.

MEDICAL SOCIETY OF LONDON. The following papers are announced as intended to be read at the ordinary meetings of this society.

Saturday, October 22nd. F. Sibson, M.D., F.R.S., "On Pericarditis."

Saturday, October 20th. Robert Barnes, M.D., "On the Various Means of Inducing Contraction of the Uterus".

Saturday, November 5th. J. R. Cormack, M.D., "On Cholera".

Dr. MARSHALL HALL AT MONTREAL. We copy the following paragraphical *éloge* from the September number of the *Montreal Medical Chronicle*, edited by Drs. Wright and MacCullum.

"This distinguished physician, who has during the last six months visited many of the cities of the American Union, arrived in this city on the 11th ultimo, and left it again on the 17th. He had previously spent some days with his professional friends in Toronto and Quebec. During his residence here, all the leading practitioners of the place, and a few from the vicinity, called upon him, and were much pleased with his urbanity of manner, easy address, and readiness to communicate on subjects which have engaged his attention during a long and active life. On the evening of the 15th, he performed a number of experiments, which will be published in our October number, in the rooms of the Natural History Society, before a highly respectable audience; and, on the succeeding evening, delivered a lecture at a conversazione held in the same rooms. At the close of the lecture, Professor Holmes, who was deputed by the members of the medical profession present, addressed Dr. Hall as follows:—'In my own name, and on behalf of my professional brethren now present, I would express to you, sir, the gratification we all feel by the presence amongst us of one who has earned for himself, by his painstaking researches and successful investigations into the physiology of the nervous system, an enduring place in the annals of our noble profession. For the opportunity to make your acquaintance, which you have afforded us in this visit; for the interesting experiments which you have performed in our presence; and for the highly instructive lecture delivered this evening; you have our sincere thanks. We shall ever recall the circumstances of your visit with feelings of pleasure; and we trust, that in the reminiscences of your tour through America, that of your sojourn in Montreal may not be among the least pleasing.'

"Major Lachlan, President of the Natural History Society, then came forward, and, presenting Dr. Hall with the honorary degree of the society, said:—'I have much pleasure in being deputed by the members of the Natural History Society of Montreal, to present you with the diploma of honorary member of that society (voted by acclamation at their last meeting), as a mark of their estimation of your well-earned high professional character, as well as of your valuable contributions to science generally, and in the hope that that document will occasionally serve as an additional agreeable memorandum of your visit to Montreal.'

"Dr. Marshall Hall replied:—'I thank you, Professor Holmes, and the gentlemen here present, and especially the gallant President of the Natural History Society of Montreal, for the kindness and the honour done me this day. My chief desire is to deserve well of my profession, and to live in the esteem of my professional brethren; and every proof that that desire has been attained, is a source of extreme gratification to me. I may well, therefore, be pleased with the events of this evening. I thank you sincerely, gentlemen, for the cordial manner in which you have welcomed my presence amongst you, and beg to assure you, that when the ocean again divides us, my visit to Montreal will be remembered with peculiar pleasure and pride.'

"The company then separated into groups, and animated conversations on various subjects of professional and literary interest, were kept up until a late hour."

THE FEMALE DOCTORS OF PENNSYLVANIA. The "Female Medical College of Pennsylvania" opened its winter session on the 1st of October. Its faculty consists of five male and two female professors; all of whom, male and female, are medical graduates. The demonstrator of anatomy is a woman, a disgusting fact which it is painful to relate. Miss (?) Charlotte Adams, of Boston, and eight other ladies (?), have received, about six weeks ago, the degree of M.D. from the Female Medical College of Pennsylvania.

STONEMASONS WITH MOUSTACHES. Numbers of masons throughout the country now allow the hair to cover the upper lip, to arrest the dust which flies off in the working of the stone, before it reaches the lungs. This, it seems, has created quite a *furor* amongst the softer sex; the masons are at present decidedly the most popular beaux.—*Caledonian Mercury*.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW. The following gentlemen have been elected officers for the year 1853-54:—Matthew Wylie, Esq., M.D., President; W. E. C. Clark, Esq., Vice-President; J. Donald, Esq., Treasurer; J. McCarron, Esq., Secretary; Thomas Christie, Esq., Librarian; James Miller, Esq., Seal-Keeper; Alexander Morton, Esq., Vaccinator; James Scanlan, Esq., William Black, Esq., James Kirk, Esq., M.D., George Lade, Esq., M.D., David Walker, Esq., and Robert Adam, Esq., Directors; John Dick, Esq., Factor; James Dougall, Janitor.

ROYAL COLLEGE OF PHYSICIANS. At the usual Quarterly Meeting of the Comitia Majora, held on Friday, September 30, the following gentlemen having undergone the necessary examination for Diploma, were admitted members of the College:—Dr. Callaway, London; Dr. Coote, Oxford; Dr. Ballard, London.

APOTHECARIES' HALL:—PASS LIST. Thursday, Sept. 22nd, 1853:—Thomas Brown, Bromley, Lancashire; Wm. Hitchin Pendlebury, Bolton-le-Moors, Lancashire.

Thursday, Sept. 29th, 1853:—Edward Vaughan, Keynsham, Somerset; William Steventon, Cheadle, Staffordshire; John Bishop King, Brighton; Stephen John Bunt, London.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

ARAGO, M. François, at Paris, on October 2.

BLAKE, Robert, Esq., Surgeon, R.N., at Park Place, Mile End Road, Stepney, aged 84, on October 7.

ELKINGTON, James Goodall, Esq., Surgeon, formerly of the 17th Lancers, at Dublin, on the 3rd instant, aged 70. He had been in the service forty-seven years, and had served through the Peninsula war and at Waterloo.

IRONS, George Robert, Esq., Surgeon, at Newcastle-upon-Tyne, of cholera, contracted in his zealous attendance on cases of that disease, aged 37, lately.

*JAMES, William, M.D., at Bristol, on October 11.

MALCOMBE, —, M.D., at Newcastle-upon-Tyne, of cholera, lately.

MERRSH, Thomas, M.D., at Brentwood, Essex, aged 47, on September 27.

MATTHEW, Joseph F., Esq., Staff Assistant Surgeon Royal Army, by the upsetting of a boat at Auckland, New Zealand, on May 13.

M'CULLOCH, John, Esq. at his residence, Liverpool, aged 96, on October 2.

MERRYWEATHER, John G. Loy, M.D., eldest son of George Merryweather, M.D., after two years of lingering illness, aged 23, on October 9.

SWAYNE, Stephen Jennings, M.D., Deputy-Inspector of Hospitals and Fleets, and Justice of the Peace for the county of Kent, at Rochester, aged 71, on September 28.

WHITTLE, Edward John, Esq., at his residence, Lamberhurst, after a few days illness, aged 71, on October 6. Mr. Whittle had been for thirty-nine years in practice at Lamberhurst; he had also been in the army, and for six years House-Surgeon to Winchester Hospital.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention, and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLIII.

LONDON: FRIDAY EVENING, OCTOBER 28, 1853.

NEW SERIES.

TO CORRESPONDENTS.

SCHÖNBEIN'S OZONOMETER may be obtained in about a fortnight from this date, by applying to Mr. John Cox, Peckham. Dr. DREW, of Southampton, is intrusted with the transmission of observations to Dr. Schönbein, as is stated in a letter from Dr. Drew, which we shall publish next week.

THE METEOROLOGICAL PAGE of the Association Journal has induced so many zealous observers in important localities to offer us their services, that we have at present under consideration the propriety of devoting next year an additional half page or perhaps even an additional page weekly, to meteorological observations. We shall be glad to receive for our private use and guidance expressions of opinion on this subject. Tabular matter is both troublesome and expensive; and unless an extension of the space devoted to meteorology be generally called for, we shall not make it.

METEOROLOGICAL INSTRUMENTS. Dr. Barker, of Bedford, has kindly undertaken to furnish, for insertion in an early number, information regarding the instruments used by himself and his fellow-contributors.

CLIMATE OF MADEIRA. The letter of Dr. Burgess has been in type for some time, and shall appear in our next number.

THE ETHICS OF THE MEDICAL PROFESSION.

THE letters in this day's number upon Medical Ethics, show that the subject is engaging attention: and the announcements of the intended meetings of the Committees on Medical Ethics and Gratuitous Advice, encourage us to hope that a new and a better order of things will ere long be instituted.

It is at least something to have recognised the necessity for amendment; and in this recognition we hail the first advance to many necessary changes and reforms, though they do not involve aught that is new in principle or action. Medical ethics are really the carrying out of the principles of self preservation and self interest. They involve no constraints but those of right feeling, and ask for no concessions but those which experience has taught to be eminently and equally conducive to the well being of society and of the individuals of which it is composed. There is little to fear in opposition—much in apathy and indifference. These are the things that bear upon the young and struggling practitioner, not on the experienced and successful physician; not on the man, whose balance at his banker's and stock invested place him beyond care, but on the country doctor, and the town general practitioner, suffering all from a competition placed beyond limit, and producing the inevitable consequence of depreciated value. In the law, no such practices are tolerated, and no such hardships exist: the public have learned, and have been taught to respect the code which governs the internal regulations of the bar; there is an acknowledged tribunal of public professional opinion against which it is in vain to war. It is not arbitrary, but is the mere generalisation of facts, deduced from experience, showing how and in what manner various contingencies can be best met, to conduce to the good of the profession and the public. This is all we have ever sought for in the medical profession, and most blind are its members

to their own interests so long as they neglect to follow a plain path leading to the correction of abuses, the sustaining of public opinion, and a more just appreciation of the rights and claims of a profession less recognised and more unworthily treated than any other body in the state. Why is this? Is it not because we have not been true to ourselves?

When the man, riding on his ass and pursued by banditti, urged him to greater speed to escape the enemy—No, was the animal's reply, the worst enemy I have ever had is the one now on my back. The worst enemy the medical profession has ever had has been found in the ranks of the profession itself; and all true reform must be from within. Jealousies and bickerings, want of union and unanimity, pride in supplanting a brother practitioner, the struggle for preference and advantage, the mere name of large attendances on the sick, irrespective of proper remuneration—these have been and are weapons daily used by the public against the profession.

Our Association has power to arrange and settle the various points of difference existing, such as no Medical organisation has ever before possessed. It has the power to make its membership a test of honour and respectability; it can create a tribunal to prevent and adjust those unseemly differences existing often for years to the entire exclusion of intercourse between fellow workers for the good of suffering humanity; it can elevate the whole status of the profession by making it more worthy to be universally esteemed and respected; and it can by its own unity show to each little knot of town-dwelling medical practitioners how they can increase their usefulness, win more extended respect, and remove the stigma of disunion and division to which they are now too often subjected.

These are great advantages which are intra-professional, and which, by regulating the conduct of each member of the Association, must tend to benefit the whole mass of the profession, and by degrees to draw all within its influence. But there are correlative advantages, in having fixed regulations for our guidance, as the public are thus made aware of what we expect and of what we shall do on all occasions. United, we are as the herd of bulls which the waiting lion could never attack; quarrelling among ourselves, we singly fall an easy prey. Boards of Guardians would in vain offer their scanty pittances for the life blood of our younger brethren, or insurance offices insult us by their subterfuges to escape a just fee, did they not feel assured that our refusal would not prevent a ready acquiescence, nay, a humble canvass for the proffered work from some medical aspirant. We again repeat it, we are not true to ourselves, or we should be more fairly and more truly used.

Our leading men who have risen over the billows and breakers of fortune's sea, and have safely landed on the shore of success, should, in justice to their younger brethren, whose hope deferred leads often onward to the grave, remember their own days of struggling and painful despondency. They should hesitate before dispensing indiscriminately gratuitous medical advice. They should pause

before they aid the prescribing druggist, and ruin the general practitioner. They should demand some guarantee that the applicants are in reality proper objects of their beneficence, and be prepared in doing to others to illustrate the golden rule, however much it might detract from the splendid levee they can afford without pay to maintain, and almost each member of which is a fee filched from the poor man's income. How many times have we had proofs of the impudent deception practised on consulting physicians in their chambers? How many, who as out-patients have procured gratuitous advice at a London hospital, have been found able to pay, when they could no longer avoid medical attendance at home? We know of cases in which such persons have given their fee of £20 or £30, for the attendance of the very surgeon under whose care they had meanly placed themselves to obtain gratuitous hospital advice!

THE AMALGAMATION OF SOCIETIES.

We are glad to observe that the *Lancet*, in a leader of last week, advocates the great principle for which we have so earnestly contended; viz., the establishment of a Medical Institute in the metropolis, from which shall branch out sections for pathology, physiology, and other departments of science.

That many obstacles lie in the way to retard such a combination is very evident; but there are none that might not be overcome by judicious management, mutual concession, and friendly feeling. Indeed, the divisions that now exist are but divisions in appearance. The man who belongs to all the leading London societies feels as though he were a member of one only; except when he grudgingly pays to each the subscription, the aggregate making a sum which he well knows would be only one half in amount, and paid with much less trouble, if the divisions did not exist.

There are some who think that the honour of a separate society would be diminished by its being reduced to a section, and that its influence would be in some degree lessened. This is a most grievous mistake. If one great central body was formed out of the sections, and on the representative principle, the highest medical honours in the land would be opened for competition; while the separate honours pertaining to each section would remain just as important as those now open to the members of the several societies. The presidency of the pathological section, for example, of the London Academy of Medicine would surely be as honourable an office as is the presidency of the Pathological Society.

If anything can add force to our arguments, it is the fact that the plan we advocate has already been found eminently successful in the management of the British Association for the Advancement of Science. Indeed, the plan is so simple and so obviously necessary that we wonder it should have been left untried by the members of medical societies until so late a day as the present.

However, it is not now so incumbent on us to criticise the past, as to point out a line of action for the future, by which the combination so much to be desired may be obtained. This we shall continue steadily to do; and if our contemporaries will also persevere in advocating the same principles, we are certain that the reform hinted at will soon be accomplished, despite all the class interests and dogged prejudices that threaten to rise in snarling opposition.

THE MEDICAL PROFESSION AND THE BRITISH CONSTITUTION.

TO-DAY we publish a few of the many letters which we have recently received regarding the Vaccination Act, selecting chiefly those which refer to its details. It would serve no useful purpose to print pages of complaints against Government for allowing this measure to pass through Parliament; for the *ASSOCIATION JOURNAL* has already contained ample exposures of the unconstitutional character of the Act, as well as of the glaring deficiencies of its machinery for accomplishing an extension of *efficient vaccination*, the object for which it was said to be framed. It seems, moreover, to us, that as writing and petitioning have done us no good in the past they need not now be relied on in the future. Unless the zeal of our complaining colleagues can achieve something more than petitions and "letters to the editor", we confess that we despair of seeing the medical profession included within the pale of the British constitution. The apathy, if not the treason of our colleges, and the consequent want of organisation of the general body of the profession, have rendered us an easy prey to crude and pragmatical statesmen. The medical press with united energy craved delay, and denounced the injustice and showed the uselessness of the Act; but, as medical men can command no votes in the House of Commons, and take no part in politics, just and temperate remonstrances were disregarded. Nay, in return for our deeds of true philanthropy we have been singled out for insult and oppression; we have been selected from among our fellow citizens as a body to whom alone is inapplicable the maxim, that "the labourer is worthy of his hire". An Act of Parliament has been passed by which it is declared that the failing to render to the State, gratuitously, certain most important professional services is "a misdemeanour", a crime subjecting us to fine and imprisonment! We appeal to the expounders of British constitutional law if we are not correct in saying that Parliament had no right to pass an enactment so monstrously tyrannical? We appeal to the gentlemen of the House of Commons themselves, if they would have dared to enforce, or even suggest the idea of enforcing gratuitous work upon lawyers, clergymen, or any body of men possessed of political influence? In conclusion, we advisedly, and without hesitation, concur with Mr. Bloxam in saying that the Vaccination Act of 1853, as regards the medical profession, interferes more oppressively with private business than any law which has been attempted to be enforced since the year 1688.

The only way in which this grievance can be removed, and the just rights of the medical profession defended from farther aggressions, is by a combination of unselfish, zealous men determined to introduce into the House of Commons a number of medical members, apt in business, and true to their profession. This object, if rightly sought after, might ere long be attained; and the attempt, even though abortive, would do good, inasmuch as it would call forth on our behalf the generous sympathies of enlightened portions of the community. At all events, a resolute trial in this direction ought to be made, for the past has abundantly shown that our claims cannot get fair hearing in high places, in virtue of letters, leaders, petitions, and deputations.

ORIGINAL COMMUNICATIONS.

ON THE CAUSES AND TREATMENT OF DIARRHŒA.

By THOMAS HUNT, F.R.C.S., etc.

THE frequency with which diarrhœa degenerates into malignant cholera invests the treatment of the former with an unusual interest and importance at the present time; and reflective practitioners may not feel altogether satisfied with the directions which have issued from medical or sanitary boards, or other pseudo-professional authorities. Nor can we claim more respect for the somewhat dogmatic and earnest style in which the zealous scribblers in our periodicals have urged us to adopt respectively their own favourite mode of treatment of choleraic diarrhœa, or cholera itself, in *all* cases. Yet these proposals for an exclusive line of practice are so numerous, and at the same time so contradictory, and often proceeding from sources so respectable, that I have thought a temperate and considerate discussion of the subject, on the part of those members of the Association (if such can be found) who have no *panacea* to propose, might be useful to the cause of science, and might serve to check that unhappy tendency to routine and empiricism which has of late so much damaged the profession in the eyes of the public.

Although I have nothing to propose which is absolutely new, I believe that, if I can induce my brethren, one and all, to recur to first principles, to listen to the suggestions of anatomy and physiology, and to reflect upon the general economy of the alimentary canal, instead of being carried away by the wild theories of disease which modern clamour has thrust so importunately upon us, I shall have accomplished more in reforming the treatment of diarrhœa than by anything I have myself to propound.

In the first place, it must be remembered that a periodical discharge from the bowels is natural and necessary, and that, when this discharge becomes excessive, it constitutes not a disease, but a symptom only, and not always a *symptom of disease*. In a healthy condition of the system, the alvine evacuations are proportioned, *ceteris paribus*, to the quantity of effete matter contained in the bowels. If this quantity is excessive, either from gluttony or any other cause, there is, or ought to be, as a natural consequence, a discharge proportionably excessive. If the bowels become loaded with indigestible matter, with acrid poisons, or with irritating secretions, their discharge is effected by a more energetic alvine action, by increased peristaltic contraction, and, generally, by augmented serous effusion, whereby the injurious matters are washed away; but, of all things, the most useful occurrences in these cases are the spasmodic muscular movements of the intestines, which are naturally excited, in order, preëmporarily to get rid of the enemy. This was well understood by Cullen; who, nevertheless, feeling it necessary to class diarrhœa amongst actual diseases, placed it in the class *neuroses*, order *spasmi*.

It is not to be denied that griping pains and diarrhœa may both exist, as idiopathic affections derived from irritation in the nervous centres, rather than in the extreme filaments; but with such cases of diarrhœa we are seldom called upon to deal—never, perhaps, as epidemic disorders; and, therefore, for the present, our attention may be confined to cases in which there is or has been manifestly, in one form or another, a *poison in the bowels*. This poison, whether it be a specific poison, or simply effete, indigestible, or acrimonious matter, is, in simple diarrhœa, always found creating the disturbance first and chiefly, if not exclusively, in the small intestines. This requires no proof. It must be plain to all who reflect on the structure and functions of the small intestines, in contrast with those of the larger bowels, that bilious or serous diarrhœa always commences in the upper portion of the canal; while dysentery, or mucous diarrhœa, affects the lower and larger portion. Moreover, it must be borne in mind that the small intestines are

much more easily excited by the presence of acrimonious matters than the large. This accounts for the sudden cessation of diarrhœa which often attends the administration of a single dose of calomel, rhubarb, or other purgative, the action of which on the liver, stomach, or duodenum, removes the *materies morbi* from the upper to the less sentient lower bowels, which then remain for hours inactive, because unexcited; the smaller intestines being meanwhile relieved from their distress. Now, if, in such a state of things, the disordered action of the bowels should be erroneously attributed to a relaxed condition of the exhalents, and the patient be treated accordingly with astringents, absorbents, opiates, and stimulants, one of two things must happen—either the disorder proceeds, in spite of these remedies, which often happens; or, the escape of the poison being prevented by the medicines employed, it is either absorbed into the blood, to damage the whole system, or it is retained in the intestines, to excite future irritation there. Without doubt, opiates and astringents are sometimes useful in diarrhœa: it is against their indiscriminate administration that I protest. Some rule should be observed as regards the remedies required, or we shall often do mischief, and always be guilty of empiricism; and the design of this paper is chiefly to propose a few rules for adoption or rejection, by which the Association shall agree to be guided in their treatment of diarrhœa, more especially in choleraic times.

The first practical question arising in every case is, Is the diarrhœa complicated with frequent vomiting? This must determine our practice in the first instance; because, in such a state of the stomach, it is almost certain that every medicine intended to check the action of the bowels will be immediately rejected; and thus, in country practice, many valuable hours will often be lost, and no arrest of the disease will have been effected. The vomiting must first be stopped. How is this to be done? Practitioners vary a good deal in their practice; but it may be laid down as an excellent rule, that, unless we are sure the vomiting is useful, it cannot be too soon arrested. If the natural contents of the stomach have been first ejected, followed by bile, first yellow, afterwards brownish green, the patient will be liable to sink from the vomiting alone, which can generally be effectually checked by a simple effervescing draught containing a small excess of alkali, and from half a drachm to a drachm of compound tincture of cardamoms, every two or three hours. If this fail, which it rarely does, a drop of creasote, mixed with twenty drops of the tincture of cardamoms, and given in about a teaspoonful of water, will have great control over the stomach, and prove a good accompaniment of calomel and opium, or any other remedy designed to reach and act upon the bowels.

The vomiting being stopped, the next inquiry will be directed to the cause of the diarrhœa. If it should prove to be bilious, the case is one of English cholera, and is liable to run on into the "spasmodic" form, without becoming either "Asiatic" or "malignant". Severe gripings and occasional cramps in the gastrocnemii and other muscles, with rapid prostration of strength, are symptoms which have always accompanied severe attacks of the old fashioned English cholera morbus; and in former times, a dose or two of magnesia and rhubarb, with copious libations of weak broth, were all that were required (with the addition sometimes of a moderate dose of laudanum), to put the patient into a state of convalescence. One does not see why the same principle of treatment should not now be adopted for bilious diarrhœa. The rhubarb and magnesia were designed to remove the offending material from the stomach and duodenum into the colon and rectum; the broth to dilute the bile and shield the mucous membrane from its acrimony, and to afford support and nourishment, when solid food cannot be taken; the laudanum (which was the least important), to moderate the cramps.

But it should be borne in mind that there are many other causes of diarrhœa, besides this excess of the hepatic secretion; and several, or all of these causes may be in operation, as well in choleraic seasons, as at other times; and nothing can be more unphilosophical or practically unwise, than to

assume that every case of diarrhoea which occurs during the prevalence of malignant cholera, is necessarily choleraic in its character, much less that it ought to be treated *specifically*. A general survey of a few only of the causes of diarrhoea in their ordinary manifestations, will show the absurdity and danger of the routine practice, especially when that practice consists of the indiscriminate exhibition of opiates and astringents, as in some degree sanctioned by the Board of Health in 1849.

Diarrhoea may arise,

i. From the presence of irritating substances in the small intestines, which may consist of or arise from,

1. Excessive quantities of their natural contents:

- a. Bile.
- b. Pancreatic juice.
- c. Intestinal secretions.

2. Deficiency of one of them, rendering the others offensive: *e. g.*, when the bile is deficient the other sections become irritating from their excess of acid.

3. Food transmitted through the pylorus in an undigested condition.

- a. From excess or indiscretion in eating or drinking.
- b. From disease or debility of the digestive organs.
- c. From sudden arrest of the digestive process, arising from mental emotion or accident.

4. Acid secretions, the result of impaired or imperfect digestion.

- a. Acid in excess.
- b. Alkali in excess.

ii. From the presence of a poison in the blood, which may have been conveyed thither by the stomach, the lungs, or the skin.

1. Animal poison.

- a. Specific.
- b. Putrid animal matter.
- c. Effete human secretions or excretions whether putrid or otherwise.

2. Vegetable poisons, specific or putrid.

3. Mineral poisons, used as medicines, or otherwise conveyed into the blood.

iii. From suppressed evacuations, or from congestion or irritation in some distant organ.

iv. From actual inflammation of the mucous membrane of the small intestines. (The discharge produced by inflammation of the large intestines constitutes dysentery.)

v. From atony or relaxation in the exhalents of the bowels, generally chronic, but occasionally the result of acute diarrhoea in an advanced stage.

1. Arising from senile debility.

2. ——— disease.

- a. Typhus.
- b. Phthisis, etc., etc.

The above are by no means all the causes of diarrhoea met with in practice, but they constitute its more frequent causes. Now, what is the pathology of diarrhoea? In four out of the five divisions in this simple table, it is obvious that in every case the diarrhoea is remedial and protective to the system; it is simply natural defecation regulated by the more or less pressing necessities of the case; a salutary discharge, which if prematurely checked, is liable to poison the blood, or to arrest altogether the digestive process, if not to produce organic inflammation or fatal disease. He, therefore, who would treat this disorder *indiscriminately* with acetate of lead, sulphuric acid, or any other astringent, or with confection of opium, or any other sedative, is, to say the least, a very incompetent and indiscreet practitioner, and no authority under which he can shelter himself can either bear him harmless or afford a plea to palliate his conduct. Equally censurable is the man who would treat every case with purgatives, calomel, sulphur, or any other specific; inasmuch as it is impossible that any one mode of treatment can be applicable to the many causes and conditions which may be concerned in augmenting the alvine secretions.

It is requisite to bear in mind, likewise, that there is, in different individuals, a very great variety in the frequency with which the bowels act in health. Some persons are never well unless the bowels act twice, thrice, or even oftener in the twenty-four hours; others are in excellent health although the alvine evacuation occurs only once, twice, or thrice in a week. When the latter are seized with cholera there is generally no premonitory diarrhoea; whereas those whose bowels are naturally loose are not unfrequently forewarned, or even protected from cholera by a smart attack of diarrhoea, the poison being eliminated by the bowels. I will not assert that it is *always* dangerous to check by opiates and astringents a diarrhoea, which, for any thing we can tell, may tend to dislodge an otherwise fatal poison; but current notions run so much the other way, unchallenged, that it may be as well to consider and reflect before adopting and acting upon a merely popular theory.

In considering the causes of diarrhoea as above sketched, and regarding it, as a general rule, as a salutary effort of nature, it would appear that the best practice would be to a certain extent to encourage it, or else to let it run its course. With regard to the latter alternative, in ordinary seasons it seldom happens that neglected diarrhoea in adults comes to any serious harm, but the experiment is seldom tried to any extent. When, however, diarrhoea is epidemic, and in many cases fatal, it is manifest that the expectant treatment may turn out to be little better than manslaughter. With regard to the purgative treatment of diarrhoea, with a view to dislodging more peremptorily and effectually the offensive material, when such exists, it cannot be doubted that there is much sound philosophy and good reason in the proposition; and when the cause of the disease is correctly diagnosed, and the purgative properly selected and given in a suitable dose, there is certainly no treatment which so suddenly and effectually puts a stop to the disease. And here I should be guilty of great disrespect to our intelligent and zealous associate, Mr. Conway Edwards, of Batheaston, if I omitted to notice a short but pithy tract, *On the Purgative Treatment of Spasmodic Cholera*, published by him (at Bath) during the cholera epidemic of 1849. He uses calomel, jalap, scammony, and sulphate of magnesia, not only fearlessly, but, as he tells us, successfully. The cases which he has published would be now generally called choleraic diarrhoea, and therefore belong to the category under review. Mr. Edwards found the purgative system always effectual; but he combined with it small doses of laudanum, and other reasonable adjuvants, as the case might require. It is not consistent with my object to hold out any special plan of treatment; but if there is reason to suspect the case to be one in which the diarrhoea is excited by the presence of something irritating the small intestines, the question is, What is the most ready method of carrying the offending matter into the large intestines, where it will probably remain for a time in a quiescent state, and the bowels will be no more disturbed? There are some medicines which act on the lower bowels only, as aloes and colocynth; others, as rhubarb, calomel, and perhaps magnesia, act on the small intestines only. Rhubarb seems to have a specific action on the stomach and duodenum; and calomel, by stimulating the liver and pancreas, supplies the duodenum with a purgative dose of bile diluted by the pancreatic juice. A dose of calomel and rhubarb, therefore, consisting of about three grains of the former and five of the latter, will at once stop a diarrhoea of this kind. I have tried it in a thousand instances, in many of which stimulants, opiates, and astringents had failed; and it almost invariably stops the discharge, either immediately or in a few hours. Other practitioners use magnesia and rhubarb, castor oil, &c., and with so much success, that they are tempted to conclude that purgatives are the right medicines for diarrhoea, when they are, when the cause is removable, removable only then. Is the choleraic diarrhoea of this kind? If so, why does it yield frequently to check?

have a tendency to lock up in the bowels the supposed source of irritation?

This is the precise question to which I would earnestly direct attention. The premonitory diarrhoea which rages in cholera-smitten districts is *not* a diarrhoea *sui generis*: it depends on various causes in different individuals; and, although it may generally be treated successfully, no treatment can be trusted, which does not proceed upon an intelligent perception of the cause existing in the individual case.

1. In a large majority of these cases, the chief cause is *panic*. Neither men nor women will confess it; but the family and friends observe it, and know it. Among the weak-headed and idle, who always abound where cholera rages, a large proportion are absolutely horror-smitten at the cholera when once it invades their dwellings or their immediate neighbourhood. And who does not know that both the bowels and the bladder are more readily excited by fear to discharge their contents, than by any other stimulus? Then, sympathy with the attacked directs the attention of those around (unconsciously, it may be) to their own abdominal movements and sensations, and thus excites over action. Anxiety and fatigue, night watching and nursing, all lend their aid to relax the bowels; and bowels so relaxed are easily quieted by taking almost any medicine whatever, which the patient expects will control the complaint; and those which, besides acting on the mind, give a sensible glow to the stomach, are still more certain. Hence, brandy, tincture of rhubarb, laudanum, chalk, cinnamon, cardamoms, *et hoc genus omne*, will often cure the "premonitory" symptoms, and thus, *as we are told*, prevent cholera in a whole neighbourhood.

2. Dyspepsia, from intemperance or other causes, may have irritated the bowels, and some offensive matter requires to be removed. In this case, astringents, opiates, and stimulants, all do harm. Here the calomel and rhubarb plan will succeed best.

3. Exposure to cold, want, or wet, may have excited mucous inflammation. Here the hot sand, salt, or flannels, the mustard cataplasms and fomentations, the warm bath, castor-oil and Dover's powder, are the remedies. And there are cases in which fear, dyspepsia, and cold, have each their share in relaxing the bowels; and these are cases which are liable to run on to cholera. The neglect of any part of this treatment may then be wrong. *In the first instance*, it is very important that any offending material should be removed; and in practice it is almost certain that a dose of calomel and rhubarb will more or less check the disease; but this should be speedily followed up by the external application of heat to the whole abdomen, spine, and extremities; by effervescing drinks mingled with aromatics, if sickness supervene; and ultimately, if the diarrhoea persist, by chalk, opiates, and astringents. Some practitioners prefer the mineral acids, which exercise an immense control over the diarrhoea, which results in mere relaxation of the vessels, or in an excessive effort of nature to expel the enemy.

But, 4. The choleraic poison itself may have taken up its abode in the blood or bowels of the patient, producing, in the first instance, a severe diarrhoea of the bilious character, and then, in a very few hours, a frightful discharge of serous fluid, without, *as yet*, any other symptoms of epidemic cholera. What will stop *this* "premonitory" diarrhoea? Will chalk or opium, lead or catechu, calomel or rhubarb, sulphuric acid or sulphur, brandy or salt, baths or bleeding, hot air or hot sand, or any other plans or appliances which ingenious practitioners have invented, and sanguine practitioners publicly vaunted—will any of these "prevent" the cholera, and save the patient? I doubt it much; but I would try them all, not blindly, but in obedience to the movements and dictates of nature. Supposing there is no vomiting, I would administer *first* a full dose of calomel and rhubarb; for it cannot be doubted that *here* there is a poison to be discharged, or the patient must die. Next, I would follow the instincts of the patient as to diet. Let him drink any quantity he likes of any fluid he prefers:

cold water, salt and water, and cider, are generally the drinks he looks for; and, to the application of external heat, friction should be added. When the purgative has had an hour or two to perform its work, astringents and opiates may be given. But of opiates I would be very shy; the cramps of the limbs are but efforts of nature to accelerate the venous circulation, and to hurry along the treacherous stream towards the right ventricle of the heart, where it is less likely to stagnate than in the veins; and opiates are apt to check these salutary efforts. But I am now trenching on the treatment of cholera itself, on which more has already been written than I have had time to read.

Alfred Place, Bedford Square, Oct. 8, 1853.

MADEIRA AS A RESIDENCE FOR INVALIDS:

WITH A SERIES OF METEOROLOGICAL OBSERVATIONS
MADE IN THE ISLAND.

By F. D. DYSTER, M.D.

I HAVE read with great interest the paper on the "Climate of Madeira", in the *ASSOCIATION JOURNAL* of September 2nd; and, if I now publish a few remarks on the same subject, it is not that either the facts are doubtful, or Dr. Lund's paper incomplete, but that I desire to add, if possible, to the weight of his testimony, and to diminish the probability of any phthisical patient, to whom this wonderful climate of Madeira is likely to prove useful, being intimidated or misled by the assertions of Dr. Burgess.

The table of meteorological observations which I append applies to the year 1844; and the observations were *all* made by me.

The means for the year, excepting the latter part of June, all July, August, September, and October, were obtained at Funchal, in a house about 250 feet above the sea level. The barometer was *within* the house, at a south window, always open; the instrument a mountain one of Bate's. The register thermometer and the hygrometer (Mason's) were placed at a north exposure, and, as nearly as can be, free from foreign influences. The tables were kept for my own amusement, little expecting that any one would ever be found hardy enough to assert that the climate of Madeira was damp and variable. I possess in perfection the tendency of John Bull to grumble at climate, and therefore all my bias was to grumble when I could. The opportunities were rare enough.

During the months of June (the latter part), July, August, September, and October, I and my meteorology removed into the mountains, about 2,500 feet above the sea; but even there Dr. Burgess would be a long time before he collected enough dew to wash his face with.

The tables speak for themselves; and the only comment I will offer is a comparison between the absolute mean dryness of England and of Madeira in 1844. The number of days on which rain fell was eighty-four: I believe five above the average. Out of these eighty-four, on twelve the rain occurred at night, and invalids ought to have had nothing to do with it. During the seven years I was in Madeira, I once, and once only, saw 42° registered on my minimum thermometer; and my lamented friend Dr. Renton told me that, in his previous experience, he had only once seen the same.

My own history tells a favourable tale as regards Madeira. In 1838, I had pneumonia, being at the time suffering from disease of the antrum, which destroyed the greater part of the upper maxillary bone. The pneumonia terminated in gangrene. The winters of that year and of 1839 were spent in two rooms. I was worse in the autumn of 1840, and resolved to go to Madeira. Some of my kind medical friends advised it; others (one especially of the most eminent in London) recommended me to stay at home. I should die in three months any where, he said; and I should debase more comfortably in England. His dia-

gnosis was wrong; but his prognosis was perfectly fair, on a single examination. My left lung was as solid as a board, excepting a cavity as big as an orange, which the sphacelated lung had left. The upper part of the right was deeply congested, and did little or no work. I was in the last stage of emaciation, spat half a pint of pus a day, had hæmorrhage about every fortnight or three weeks, with bits of necrosed bone coming away from my jaw continually. But I had a capital stewpan to set against these things, which never failed in its duty; and a great indisposition to sympathise constitutionally with local irritations.

My first year in Madeira enabled me to "hold my own". At the commencement of the second, I made a great and sudden stride towards health. My third found me free from all symptoms, and able to live and do as other people. In 1847-48, I went to Pau; and since that time I have remained in England, and find myself able to do as much as most, and more than many. It is true, I believe, that I had no tubercles; but my lungs required, after the rough assaults they had sustained, entire repose, and the removal of all atmospheric causes of irritation; and in Madeira they found it. During my first winter there, I was only kept in doors by weather on *three days*. What is said in Dr. Burgess's book about dew, is a ludicrous blunder. I do not think I saw dew twenty times in my *town* garden, in seven years, and a comparison of the range of temperature with the dew points will explain this.

With regard to the frequency of phthisis among the Portuguese, I am disposed to believe it to be greater than Dr. Renton supposed. But this is easily accounted for without my attempting to impugn the correctness of that accurate observer and skilful physician. The poverty of the

people has progressively increased, and tuberculosis with it. Hard work, scanty food, insufficient clothing, damp windowless houses in the mountains, dark dirty ones in the towns, are all powerful allies of phthisis, and the frequency or rarity of its occurrence among the Portuguese does not apply to the question on which Dr. Burgess brings it to bear. It only proves that climate *alone* will not prevent tubercular disease, which no sane man ever supposed to be the case.

Some returns sent to Mr. Robertson, of Manchester (*Edinburgh Med. and Surg. Journal*, Oct. 1846), on the period of menstruation among the lower classes of Portuguese, point to the existence of the same condition which favours the development of phthisis. The average age at which 144 girls first menstruated, was (if memory serves me) fifteen and a half. If these had been well nourished, well lodged, and well clothed, there is no doubt that puberty would have been accelerated, as it is among the easy class both of Portuguese and English residents.

The fatal event of many phthisical cases sent to Madeira is to be accounted for on the grounds indicated by Dr. Lund; namely, an exaggerated opinion of the power of climate, in looking upon it not as a therapeutical agent, but an anti-pathological one, leading invalids to neglect all hygienic precautions, which are as needful in Madeira as in England, and in the fact that cases are sent out when advanced into the third stage. But in the latter case, though cure may not be reasonably expected, the descent to the grave may be greatly smoothed. A brother-in-law of my own who died in my house, spent some hours of the day preceding his decease in my garden, and that, at a period of the year, when exposure to the external air would have been out of the question in England.

During the months marked thus (*), the observations were made at about 2,500 feet above the sea level. The others were made at Funchal at about 280 feet above the sea level. None of them are corrected. The instruments were a mountain barometer, and double register thermometer by Bate, and a Mason's hygrometer.

Tenby, South Wales, October 17th, 1853.

PERISCOPIC REVIEW.

CHEMISTRY.

MILK AND ITS CONSTITUENTS.

This secretion has not met with that amount of attention, lately, that its importance, and the means for investigation now at the command of the physiological chemist, would seem to invite. Before noting, however, what has recently been done in this division of organic chemistry, it may not be amiss to detail a few of the accepted facts respecting this liquid, since these may lead to a readier comprehension of what will follow.

First, then, as to colostrum, and the distinction between it and milk: in colostrum there is not merely an increase in the amount of the saline constituents to twice or thrice of that existing in healthy milk, nor a general augmentation of the solid constituents only, in the ratio of about 17½ to 11, and which is, according to Simon, principally due to the increased quantity of sugar, although this point is not absolutely determined; but the difference mainly depends on the presence of granular masses, termed *colostrum corpuscles*, which are invariably present in the colostrum, but disappear, as a rule, in three or four days after delivery, being apt to reappear on the supervention of any acute disease. These colostrum corpuscles are much larger than the true fatty milk globules, and consist of small fat globules imbedded in an albuminous substance; whilst, as they

exist in larger quantity in the colostrum, than the milk globules do in healthy milk, the former secretion is really richer, than milk is, in fat.

In healthy milk the amount of butter varies according to circumstances, but appears to average nearly $3\frac{1}{4}$ per cent.; this butter is considered to be richer in olein than the butter from cow's milk. The valuable observation of Simon may be remembered by some, that the butter undergoes no appreciable change in amount during suckling, but that the milk-sugar diminishes with the growth of the child; whilst the proportion both of the casein and the saline constituents are augmented. L'Heritier formerly detailed some singular analyses of the milk from two women, both twenty-two years old, one dark, the other fair, from which it appears that not only the quantity of butter, but of almost all the other constituents also, was nearly doubled in the milk of the *brunette*; this assertion is well worthy of a further investigation to support or confute so singular a statement. In ordinary cases, milk contains about $3\frac{1}{4}$ per cent. of casein, and 4 to 6 per cent. of sugar; one peculiarity about the casein being, that it is less readily coagulated by acids than that from cow's milk. The above remarks apply especially to human milk.

The existence of albumen, or an analogous form of free casein coagulable by heat, in healthy milk, is disputed by M. LIEBERKUH, who has recently investigated this subject, as well as the relations of casein and albumen to potash. He finds that when albuminate of potash is gently evaporated on a water bath, it gradually decomposes into potash, and albumen in an insoluble state; and that the corresponding potash compound from milk, by a similar treatment, undergoes a similar decomposition, separating into alkali and an insoluble skin of casein. With perfectly fresh milk the results are precisely similar, the coagulum being insoluble in boiling water. The substance noticed by Scherer, existing in milk, susceptible of coagulation and having an albuminous reaction, is not only obtained by adding excess of lactic or acetic acids to milk, and heating the filtrate, but also from the filtered liquor of boiled milk similarly acidified. Boiled milk, when evaporated, as well as fresh milk, when concentrated at a temperature of 104° F., and the residuum treated with cold water in both cases, yields a liquid which coagulates on boiling. From these conditions M. Lieberkuhn contends that milk contains neither albumen, nor free casein analogous to it, coagulable by heat. This chemist further observes that the nitrogenous substance contained in fresh milk exists under three distinct forms: one corresponding to albuminate of potash, another coagulable by heat, and a third separable from the serum by filtration. He also points to the probable identity of albumen and casein, but abstains from the avowal of any decided opinion on this point.

In addition to the chlorides of sodium and potassium, the alkaline and earthy phosphates (bone earth), and the alkali combined with the casein in milk, Dr. G. Wilson, pursuing the track of some experiments of Mr. Middleton on the constant presence of fluorine in bones, recognised some two or three years since the existence of this element in cow's milk, cheese, and whey, existing probably as fluoride of calcium. We do not know that it is present in human milk, nor are we aware that experiment has yet shown that this, although most probable, is an actual and ascertained fact. Fibrin, hæmatin, urea, etc., have been recognised in milk; but these are the products of disease, and cannot be reckoned among its constituents.

PARALBUMEN.

As if still further to complicate the question of the identity of albumen and casein, above noticed, Dr. J. SCHERER describes an albuminous substance exhibiting marked differences from ordinary albumen; and which, be it really a distinct animal principle, or simply modified albumen, he has designated by the term *paralbumen*. It is met with in the fluid contained in the cysts in ovarian dropsy; these, on operating, yielded a slightly alkaline frothy liquid, capable of being drawn into threads, and which, when mixed with water and allowed to stand, deposited a little sedimentary matter.

This aqueous solution gave a copious precipitate with nitric acid, insoluble in excess of the reagent; with a little hydrochloric acid, no alteration was observed, but in large excess the liquid became turbid. Acetic acid exerted no action on it, but when ferrocyanate of potash was added to this mixture, a copious precipitate fell. When the diluted liquid was boiled, it turned somewhat milky, and then on the addition of acetic acid it yielded a flocculent coagulum, but without the liquid clearing and readily filtering as is the case with albumen; on the contrary, it remained quite turbid. With alcohol, the liquid yields

an abundant precipitate, which, after washing with alcohol, is almost wholly soluble in water at about 95° F., which aqueous solution exhibits characters identical with those described as belonging to the original liquid. It affords evidence of the presence of sulphur by the usual tests.

It would therefore appear that the contents of the cysts in ovarian disease contain a substance, differing from ordinary albumen by the solubility in water of the alcoholic precipitate, and by its imperfect coagulation when boiled with acetic acid; in its other proportions it resembles the albumen of eggs, serum, etc.

Dr. Scherer mentions that it somewhat resembles an albuminous substance observed by Bernard in the pancreas, but which coagulated by heat.

PROPYL, PROPYLAMIN.

COD-LIVER OIL. M. WINCKLER has submitted this valuable medicine to a careful examination, which has resulted in up-setting the notions propounded by some iatro-chemists, that the efficiency of this remedy depended on minute traces of iodine and bromine compounds, or such substances as the Gaduin of Dr. Jongh, by pointing out that cod-liver oil is constituted with a specific base differing from that of most oily and fatty bodies.

According to M. Winckler, in cod-liver oil the ordinary basis or radical of oils and fats, glyceryl ($C^6 H^9$), is replaced by propyl ($C^3 H^7$). When saponified by potash, this oil furnishes oleic and margaric acids. A mixture of twenty-four parts of cod-liver oil, twenty-four parts of water, and six parts of caustic potash digested together for several days and then distilled, after adding twenty-four parts of water, afforded oxide of propyl. With oxide of lead, margaric and oleic acids were obtained, but no glycerin, in lieu of which a new acid, propylic acid, was produced.

This chemist finds that whale-oil soap, when distilled with quick-lime and muriate of ammonia, yields *propylamin*. Fresh urine distilled with lime affords this ammoniacal base; which is also obtained when ergotin is distilled with potash, existing in the diseased grain, in his opinion, as a formate of propylamin. Dessaignes has recognised propylamin in *chenopodium vulvaria*, in which it occurs with a protein compound.

INOSITE, OR FLESH-SUGAR.

To procure this substance, Dr. J. SCHERER, who first noticed its presence in the muscular fluids, directs that the mother liquor from which kreatin has been obtained, and which, in the usual mode of preparing that constituent of flesh, contains an excess of barytes, should be treated with sulphuric acid so as to separate this earth, taking care that there shall be a little barytic salt undecomposed, rather than an excess of sulphuric acid. The soluble compounds of barytes with the fatty acids are thus decomposed; and these acids must be removed by digesting the liquor with ether. When the ether comes away colourless, alcohol is added to the liquor, and the mixture allowed to repose, when large crystals are gradually deposited, which may be purified by solution in water and slow re-crystallisation, when the *inosite* is obtained usually in stellar or mammillated groups of crystals.

In dry air or in *vacuo*, inosite effloresces, losing about seventeen per cent. of water; in this state, it may be gradually heated till it fuses into a transparent liquid, which by rapid cooling forms a crystalline mass, but by slow cooling remains amorphous. Crystals similar to those at first employed may be procured by solution of the fused inosite in water; showing that it has simply been subjected to dehydration. Inosite is readily soluble in water, less so in weak spirits, but insoluble in ether and alcohol. Sulphuric acid decomposes it, but not if diluted. The alkalis and alkaline-earths exert no action upon it. With sulphate of copper and potash, the usual characteristics of the presence of starch-sugar are manifested. Its peculiar and characteristic reaction, however, appears when heated on platinum foil with nitric acid almost to dryness, to which chloride of calcium and ammonia are to be added, and the mixture evaporated to dryness, when a *rose-red tint* will be manifested. If the nitric acid solution be slowly evaporated in the water-bath and the residuum dissolved in water and set aside in a stopped bottle, it gradually becomes mouldy, when, instead of the rose colour above described, under similar conditions it gives rise to a violet brown.

When strongly heated, inosite is decomposed with evolution of inflammable gases, leaving a carbonaceous residue, which readily consumes when exposed to a red heat in air. On analysis, anhydrous inosite was found to consist of C^{12} , H^{12} , O^{12} —a formula precisely identical with that of anhydrous grape-sugar, or glucose, from which, however, it is distinguished by the amount

of water of crystallisation with which it combines; the formula of crystallised inosite being $C^{12}, H^{12}, O^{12}, + 4 HO$; that of glucose being $C^{12}, H^{12}, O^{12}, + 2 HO$; the latter also representing diabetic sugar.

This inosite furnishes us with another example of the wretched state of the existing arbitrary nomenclature of organic chemistry; for who is there but would think that inosic acid, a nitro-genous compound, was derived from inosite? Their having a common source, the flesh juices, only makes the matter worse.

NEW ANIMAL ACID.

M. VERDEIL describes an acid which he has extracted from the pulmonary parenchyma: it crystallises in acicular crystals of a very brilliant aspect, and possessing strong refractive powers. This acid forms crystallisable salts with bases, and expels carbonic acid from the carbonates. It is composed of carbon, nitrogen, hydrogen, oxygen, and sulphur. The discoverer attributes an important physiological action to the presence of this acid in the parenchyma of the lungs; holding that it is secreted in contact with the carbonate of soda of the blood conveyed by the capillary vessels, and decomposes that salt, combining with the alkali, whilst the liberated carbonic acid is given off by respiration. The presence of a portion of the acid in a free state in the lungs shows it is formed there, and not in the blood, which is alkaline.

ANIMAL ELECTRICITY.

ELECTRICAL FORCE DEVELOPED DURING THE ORGANIC PROCESS OF SECRETION IN LIVING ANIMALS. In our review of DU BOIS REYMOND's work on "Animal Electricity" (p. 63), we endeavoured to sketch the progress already made in this recondite branch of physiology, and showed that good standing ground had been won, as we had attained to some clear and definite ideas with respect to the electrical currents existing in the nerves and muscles of animals, through the researches of that philosopher and his fellow-labourers.

Another step in advance has been made by Mr. H. F. BAXTER, who, in a communication to the Royal Society, details several experiments made with the object of determining whether the changes which take place during the process of secretion in animals are attended with the manifestation of electrical force: This inquiry he answers affirmatively, upon the following grounds:—

When the electrodes of a galvanometer are brought into contact both with the secreted substance and the venous blood of the secreting organ, such as the liver, the kidneys, or the mammary gland, the needle is affected in the direction which indicates the *venous blood to be positive*. The experimenter argues that this effect cannot be referred to the dissimilarity of the fluids, unless we assume that the blood was acid and combined with the secreted product; nor can it be entirely attributed to thermoelectricity, since the current varied in each organ, and was capable of passing through a liquid conductor. It may be admitted that the effects are partly due to catalytic actions on the combining power of platinum:—an idea somewhat supported by the opinion long since entertained by Wollaston, that the changes occurring during secretion are analogous to those which take place in the *decomposing cell* of a voltaic pile.

Another fact elicited was that, when one electrode was in contact with the mucous surface of the lungs, and the other with the blood in the pulmonary veins, the needle indicated the blood (arterial) to be in this case also *positive*. Mr. Baxter does not absolutely conclude from this that the lungs perform the office of a secreting organ, but observes that it accounts for his own failures, and those of Müller and Pouillet, in former experiments instituted to obtain evidence of manifestation of electrical force when a circuit was formed between an artery and a vein of the living animal, since he finds that both venous and arterial blood are positive.

Another branch of this enquiry was to determine whether any and what signs of current force are manifested during the organic process of absorption (lacteal) in living animals. It appears from Mr. Baxter's experiments, that when the two electrodes or poles of a galvanometer are respectively placed in contact with the mucous membrane of the intestine, and the chyle flowing from the lacteal of the same point, the deflection of the needle shows the *chyle to be positive*. Now, although this may be partly attributable to the changes which occur during secretion, the mesentery acting as the conducting body, it does not negative the conclusion that this manifestation of a current force is in some measure due to the changes occurring during lacteal absorption.

The results of some further experiments with respect to the

existence of current force in the muscular tissues, particularly with respect to the process of assimilation in the muscular and nervous tissues, have induced this investigator to conclude that the *muscular tissue* and *venous blood* are in opposite electrical conditions; and that the results are confirmatory of Matteucci's views respecting the origin of the muscular current. The preceding experiments of Matteucci, Du Bois Reymond, and others, show that the blood flowing from the internal jugular vein is *positive* to the substance of the brain; which, Mr. Baxter states, is also the case when the electrode is placed in contact with the muscles, or other portions of the animal, instead of the blood. From these evidences of the existence of currents in the muscular and nervous tissues of living animals, this writer contends that their manifestation is due to the changes which take place during the process of assimilation, or nutrition.

TOXICOLOGY.

DETECTION OF THE ORGANIC ALKALOIDS IN CASES OF POISONING.

At a time when the knowledge of chemistry is widely extending amongst large classes of the people, however superficial that knowledge must necessarily be, still some of the most striking facts will remain imprinted on the memory; and amongst them we may expect to find the marvellous deadly power exerted by minute doses of the alkaloids; whilst a little research would point out the many difficulties in the way of the chemist who should endeavour to determine their presence in suspected liquids. The terrible tragedy which occurred in France two or three years since, when nicotina was the agent employed, to the study of the properties and mode of preparation of which the murderer had devoted himself long previously to the completion of his crime, will recur to many of our readers. Hence there are good grounds for believing we are not combating an imaginary danger, but one which sooner or later will arise from a popular knowledge of the properties of the alkaloids; so true is it that

"Of the sight of means to do ill deeds, makes ill deeds done";

and hence arises the necessity of being prepared beforehand, so as to enable us, if possible, to trace these virulent poisons with the same certainty and accuracy with which the most minute portions of the inorganic poisons may be detected. This subject formed one of the latest occupations of M. Orfila before his decease, nicotina being the specialty—a path which has been more completely opened up by his fellow-labourer in this department of chemistry, Professor STAS, of Brussels.

It is not to be expected that medical practitioners would be competent to examine for themselves any suspicious cases; for numerous are the instances in which a skilful analyst would fail, unless, by previous special training, he had made himself thoroughly acquainted with the numerous minute precautions required in such an investigation, and the peculiar reactions and properties characteristic of each alkaloid; but the knowledge that these terrible poisons can be detected, and of the general method of analysis, is that kind of information in which none of us should be wanting.

M. Stas asserts his conviction that every chemist who has studied the vegetable alkaloids, and kept up his analytical knowledge, will not only succeed in detecting their presence in cases where they have been used as poisons, but even of the determining the nature of the alkaloid he may have isolated, provided its characteristics are sufficiently known. Amongst these he enumerates conia, nicotina, morphia, codeia, strychnia, brucia, veratrin, colchicina, delphia, emetina, aconitina, solania, atropia, and others less known, and whose claims to be classed as alkaloids are doubtful.

The method employed by M. Stas for detecting an alkaloid in a suspected substance does not materially differ from the processes usually followed, at least on the continent, to extract it from the vegetables containing these principles. He, however, cautions us, and on good grounds, against the employment either of the basic acetate of lead, or of animal charcoal; the latter is especially objectionable, for it has been clearly proved, by the experiments of Warrington and others, that animal charcoal possesses not only the property of extracting the colouring matters and smell from a solution, but also of absorbing and fixing the salts of the alkaloids, and of most other salts; so that its employment in such investigations must be always prohibited.

It appears that all the solid and fluid

mentioned above are taken up by ether, when used in sufficient quantity, from any liquid in which they may exist dissolved or suspended, and in a free or uncombined state. On this common character of this class of bodies the mode of detecting their presence depends; the conditions being, to abstract as much as possible, and by simple means, all foreign bodies; and then to add such a base to the suspected liquid as will set the alkaloid free, so that it may be taken up by the ether. Let us now suppose that we wish to examine the contents of a stomach or intestines, under the suspicion that death has been caused by a vegetable alkaloid. To these matters we must add twice their weight of highly rectified and pure spirits of wine, together with from ten grains to thirty grains of oxalic or tartaric acid, according to the quantity and nature of the substance under examination, using preferentially tartaric acid, and heat this mixture in a retort, flask, or other convenient vessel, to 160° to 170° Fahr. When cold, filter and wash the insoluble residue with more spirit, and evaporate the filtered liquid *in vacuo*, or in a strong current of air, never suffering the alcoholic solution to rise above 90° Fahr. Any fatty or insoluble substances deposited during evaporation must be separated by filtration, and the clear liquor evaporated to dryness under the air-pump. A good substitute for an air-pump is a large dish covered with a bell-glass, the external air being excluded by some oil or mercury poured into the dish; in this dish, a vessel containing oil of vitriol, or powdered chloride of calcium, must be placed, and over either of these the liquid, in a shallow glass or porcelain vessel. When the residue is thus thoroughly dried, it must be exhausted with cold and anhydrous alcohol, and again evaporated to dryness *in vacuo*. This residuum is again to be dissolved in the least possible quantity of water, and pure carbonate of potash or soda gradually added to it, until the solution is markedly alkaline, when from four to five times its bulk of ether is to be mixed with it in a stoppered bottle, and the whole well shaken together, after which it must be left to settle and clear. When the supernatant ethereal solution is quite bright, pour it into a shallow glass or porcelain vessel, and place it in a very dry place to evaporate spontaneously. In that residue, the alkaloid, if present, will be found. Should it be desired to examine the stomach itself, the liver, heart, or any other organ, we must of course chop the organ fine, treat it with rectified spirit, and proceed as above indicated.

We will now assume that one of the liquid or volatile alkaloids was present in the organ or its contents, when, on merely holding the glass or porcelain vessel, which will be marked interiorly with small oleaginous *striae*, in the hand, the warmth will cause the contents to exhale an offensive pungent odour, more or less so according to the nature of the alkaloid, and similar to that of a disagreeable ammoniacal animal scent. The alkaloid, whatever it may be, is to be redissolved in a small quantity of ether, and from one to two fluid drachms of strong solution of potash added to it, when the mixture is to be well shaken. Decant the ethereal solution, and wash the aqueous residue with a little more ether; mix with these 100 grains of water, acidulated with 20 grains of sulphuric acid; and, after shaking up the mixture thoroughly, let it subside; after which, decant the ethereal solution, and wash the residue with a little more ether. Since the sulphates of the volatile alkaloids, excepting that of conia, are insoluble in ether, this menstruum will only abstract the animal matters; the salts of the alkaloids, and even that of conia for the most part, remaining in the aqueous and acid solution. To isolate the alkaloid from this acid solution, a second treatment of this solution is required—first, with a strong solution of caustic potash or soda; and secondly, with ether again, which dissolves any ammonia which may still be present, as well as the alkaloid. The ethereal solution, spontaneously evaporated at a very low temperature, permits the ammonia to pass off with the ether; after exposing the residue to the absorbent powers of sulphuric acid, to eliminate the last traces of ammonia, the alkaloid will at length be obtained in a state of such purity, that those acquainted with the special physical and chemical characteristics of these bodies will not fail to recognise its nature.

Professor Stas speaks of having determined the presence of nicotina in the clearest manner by this process, in the blood of a dog poisoned by introducing three quarters of a cubic inch of this poison into the œsophagus. Not only were the smell, taste, and alkalinity, most strongly marked, but the chloroplatinate of the base was also obtained in its characteristic crystals. Conia was also readily detected in some very old tincture of hemlock; but of this alkaloid, ether carries off a large amount during the requisite process of spontaneous evaporation.

Should the alkaloid belong to the fixed and crystalline class, much the same method as above is at first to be followed, viz., treat the residue contained in the capsule with a little strong solution of a fixed alkali, and exhaust by rapid agitation with ether; when, if a solid alkaloid be present, litmus paper will be tinged of a full permanent blue by the ethereal solution. To isolate the alkaloid, and to procure it in a crystalline state, wash the residue left by the spontaneous evaporation of the ethereal solution with a few drops of water slightly acidulated with sulphuric acid, which dissolves both the alkaloid and any alkali which might exist, but leaves the fatty matters, etc., untouched. The acid solution thus obtained is to be evaporated *in vacuo* to about one-fourth of its original bulk, when a concentrated solution of carbonate of potash is to be added to it, and the mixture treated with absolute alcohol, which takes up the alkaloid only, and deposits it again in a crystalline form by slow spontaneous evaporation. Its nature can then be determined by means of the numerous and distinctive tests now at the command of the chemist.

These processes and results have been sanctioned by the highest authority we possessed, the late Professor Orfila, who, whilst reviewing the distinctive tests of the two volatile alkaloids which somewhat resemble each other, viz., conia and nicotina, took occasion to eulogise the labours of Professor Stas, and to state his belief that these two alkaloids may be distinguished and characterised as decisively as a mineral poison; that if present, even to the extent of a few drops, in the digestive canal, their existence may be positively demonstrated; and that, even if absorbed by the liver or other organ, still their presence may be determined.

The great beauty of these methods for isolating small quantities of the alkaloids when mixed with foreign matters, is the employment of but two reagents, alcohol and ether, in the earlier stages of the process, neither of which exert any chemical action on the alkaloids; so that the danger of the conversion of these principles into secondary products, in that primary stage (the one most likely for them to suffer decomposition), is completely obviated. It is, however, but too evident, from a consideration of the amount of these costly reagents inevitably expended in such researches, that to have originated such a method in this country, or even to follow it, unless under special circumstances, is denied to our medico-legal analysts; simply on account of the heavy cost incurred for these reagents, arising from the heavy duties to which alcoholic liquids, to whatever purpose applied, are subjected in this kingdom, and fully justifying a remark we felt called upon to make when considering the bearing of the spirit duty on medicine: "Thus British chemistry is paralysed by the pressure of this excise, and forced to occupy a rearward position in the progress of science." (ASSOCIATION JOURNAL, May 6th, 1853.)

Whilst considering these methods of detecting the alkaloids, especially the volatile ones, we may be permitted to state that Dr. F. Winckler finds a volatile alkaloid resembling, if not identical with conia, in ergotin obtained by treating the aqueous extract of ergot of rye with alcohol, etc., to which alkaloid he ascribes the effectiveness of this medicine, and not to the amorphous substance termed ergotin. Further particulars of this alleged new alkaloid would be interesting in connexion with many branches of medical science.

DISTINCTIVE CHARACTERS OF ARSENIC AND ANTIMONY.

Marsh's apparatus, in its improved modifications, enables the analyst to detect with certainty the presence of the minutest portion of the poison still most in vogue, provided due care be expended in the investigation; leaving but one question to be determined, should metallic spots be obtained from the combustion of the hydrogen, viz.: Are these spots arsenic or antimony?

To distinguish these from each other, when in very minute quantities, has, on account of the importance of the point in a forensic view, engaged the attention of many chemists. Mr. SLATER, of Manchester, a short time since, showed that when a metallic spot, deposited on porcelain from hydrogen, is exposed to the fumes of bromine, if it be arsenic, it will quickly acquire a bright lemon-yellow tinge; if antimony, it will almost instantly turn of an orange-red. A strong solution of iodate of potash turns arsenical spots fawn red and then dissolves them; whilst it has no visible action on antimonial spots until after the lapse of hours. The chlorides (hypochlorites) of soda and lime, as well as solution of chlorine, instantly dissolve arsenical spots, leaving those of antimony. This last mode Wackenroder has adopted with a view to detect arsenic in spots containing a mixture of the

metals; the spots produced by arsenic being rapidly dissolved in solution of chloride of soda, but remaining unchanged in dilute muriatic acid. Antimonial spots are soluble in neither menstruum separately, but disappear when the alkaline chloride and muriatic acid are mixed together. Small quantities of antimony in the arsenical spots render them darker and most brilliant, but do not prevent their solution in the hypochlorites, whilst in larger proportion the mixed spots of arsenic and antimony dissolve less readily, and are often eaten away only round the edges.

We quote these tests because we feel that in matters "touching life" it is wise to be armed at all points, and to be able to heap proofs upon proofs for guilt or innocence; but, for our own satisfaction, we regard the oxidation of the spots by heating them in a tube, the crystalline form of the white sublimate, and the action of heat on this sublimate, driving it up or down the tube at our pleasure, and its invariable deposition in octohedrons, as incontrovertible proofs of the spots being or containing arsenic; and, as tests, far superior to any reaction in which colour is relied upon, being free from the possibility of error arising from colour-blindness, which late investigations have shown to be a prevalent affection.

ANTIDOTES TO COPPER, ARSENIC, AND STRYCHNIA.

COPPER. M. ROUCHA asserts that calcined magnesia, in great excess, completely arrests the symptoms of poisoning, where sulphate of copper has been administered for this purpose; deducing from the similarity of the action of magnesia on all other cupreous salts, that this earth will prove an antidote in all cases of poisoning by the salts of this metal. Without controverting the truth of this assertion, we could not recommend this antidote as in anywise trustworthy on chemical grounds, and should hold it dangerous to trust to its preventive powers, till we have more conclusive authority adduced in favour of this remedy.

ARSENIC. In cases of arsenical poisoning, the hydrated peroxide of iron has now for some years been proposed as an efficient antidote, and apparently on trustworthy evidence, provided the oxide be freshly prepared and washed free from its alkaline precipitant. These two requirements sadly militate against its practical use; since much time, in such cases the most valuable of all the means at our disposal, must be expended before this preparation can be extemporaneously obtained; whilst, if kept in a pasty gelatinous state for use, its efficiency is greatly impaired, if not so seriously affected as to make the utility of the administration of hydrated oxide of iron which has been long kept, in the highest degree questionable.

To obviate these grave objections, magnesia has been recommended as a precipitant of the persalt of iron. Thus either the persulphate, or the perchloride of iron, which latter salt is to be met with everywhere in *tinct. ferri sesquichloridi*, is to be diluted and mixed with excess of calcined magnesia, the whole thrown on a cloth, and the mixture of oxide of iron and magnesia, which by this plan may be obtained in five minutes, is stated to be as efficient as the pure hydrated oxide of iron in precipitating arsenious acid and rendering this poison innocuous. We think far better of this than of the preceding suggestion respecting copper salts.

STRYCHNIA. A dilute solution of chlorine, containing about two per cent. of the gas, alternated with moderate doses of tartarised antimony, two doses of each to be administered; subsequently promoting vomiting by warm water, is the treatment advised by M. BARDER, a French pharmacist, in cases of poisoning by strychnia. He details many instances of its successful employment with dogs which had been poisoned with nux vomica. For the treatment of man, to us, who have known what it is to take a full inspiration of chlorine mixed with a large amount of atmospheric air, the remedy appears to be of an heroic nature.

ASSOCIATION INTELLIGENCE.

MEDICO-ETHICAL COMMITTEE.

The MEDICO-ETHICAL COMMITTEE of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION will meet at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Thursday, November 3rd, at 3 P.M. precisely.

W. H. MICHAEL, *Hon. Secretary.*

MEMBERS OF COMMITTEE.

ARDEN, Henry Alban, Esq., Secretary of Dorset Branch: Dorchester.

BARTTRUM, John S., Esq., Joint Local Secretary of Bath and Bristol Branch: Bath.

CONOLLY, John, M.D., D.C.L.: Hanwell.

DRAKE, Augustus, M.B., Secretary to South Western Branch: Exeter.

DRURY, T. J., M.D., Joint Secretary of the Shropshire Branch: Shrewsbury.

FEARN, T. W., Esq., Joint Local Secretary of the Midland Branch: Derby.

FLINT, Richard, Esq.: Stockport, Cheshire.

GOODE, Henry, M.B., Joint Local Secretary of the Midland Branch: Derby.

GREENHILL, William A., M.D.: Hastings.

HATTON, John, Esq., Secretary of the Lancashire and Cheshire Branch: Manchester.

HUMPHREYS, J. R., Esq., Joint Secretary of the Shropshire Branch: Shrewsbury.

HUMPHRY, George M., Esq., Local Secretary for Cambridgeshire and Huntingdonshire: Cambridge.

JONES, D. Kent, Esq., Joint Secretary of the North Wales Branch: Llangefni, Anglesey.

JONES, Ellis, Esq., Joint Local Secretary of the Lancashire and Cheshire Branch: Liverpool.

KIRKMAN, John, M.D., Secretary of the Suffolk Branch: Melton, Suffolk.

LEONARD, Crosby, Esq., Joint Local Secretary of Bath and Bristol Branch: Bristol.

MARTIN, Peter, Esq., Secretary to South Eastern Branch: Reigate, Surrey.

MATTERSON, William, Esq., Secretary to the Yorkshire Branch: York.

MICHAEL, W. H., Esq., Secretary to Monmouthshire and South Wales Branch: Swansea.

PITT, J. Ballard, M.D., Local Secretary for Norfolk: Norwich.

ROBERTSON, Archibald, M.D., F.R.S.: Northampton.

ROBINSON, J. M., Esq., Joint Local Secretary of the Lancashire and Cheshire Branch: Bolton.

SHARP, John, Esq., Joint Local Secretary of the Lancashire and Cheshire Branch: Warrington.

SYMPSON, T., Esq., Joint Local Secretary of the Midland Branch: Lincoln.

WARD, T. Ogier, M.D., Secretary of Metropolitan Counties Branch: Kensington, London.

WHITE, Joseph, Esq., Joint Local Secretary of the Midland Branch: Nottingham.

WILLIAMS, E., M.D., Joint Secretary of the North Wales Branch: Wrexham.

WOODFORDE, F. H., M.D., Secretary to West Somerset Branch: Taunton.

METROPOLITAN COUNTIES BRANCH:—COMMITTEE ON GRATUITOUS ADVICE.

The Gratuitous Advice Committee of the Metropolitan Counties Branch will meet at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, on Thursday, November 3rd, at 3 P.M. precisely.

THOMAS CHARLES, *Hon. Secretary.*

MEMBERS OF COMMITTEE.

ANCELL, Henry, Esq., Norfolk Crescent, Hyde Park.

BOWLING, John, Esq., Hammersmith.

BRYANT, Walter J., Esq., Bathurst Street, Sussex Square.

CARTER, Charles T., Esq., Hadley.

CHARLES, Thomas, Esq., Lower Belgrave Place, Pimlico.

CORMACK, John Rose, M.D., Putney.

COTTON, R. Payne, M.D., Clarges Street, Piccadilly.

FRASER, Patrick, M.D., Guildford Street, Russell Square.

HAILEY, Alex., M.D., Queen Anne Street, Cavendish Square.

LEE, Henry, Dover Street, Piccadilly.

LORD, Charles F. J., Esq., Hampstead.

O'CONNOR, William, M.D., George Street, Portman Square.

ROBINSON, Richard R., Esq., Camberwell.

ROUTH, C. H. F., M.D., Montague Square.

STEWART, Alexander P., M.D., Grosvenor Street.

TOYNBEE, Joseph, Esq., Savile Row.

WARD, T. Ogier, M.D., Kensington.

WEBSTER, George, M.D., Dulwich.

[We have been requested to state that arrangements have been made by the Secretaries of the above Committees for the meetings at the same time and Tavern, in order that a conference should be considered necessary, if deemed so. It has also been proposed that the committees dine together at six o'clock.—Ed.]

EDITOR'S LETTER BOX.

THE VACCINATION ACT.

LETTER FROM R. U. WEST, ESQ., TO THE EDITOR.

SIR,—Your facetious contemporary, Mr. Punch, has in his last number some severe remarks on a journalist who said that the reported act of the Prince of Wales at the Dublin Exhibition, in taking advantage of the hasty answer of an exhibitor, and pocketing for one shilling an article actually worth fifteen, was "worthy of the future ruler of a great commercial nation". I fear Mr. Punch has been too hasty himself in assuming that the recognised national code is a whit better than that held up to our admiration: nay, I would even maintain that the following correspondence will prove that it is not so good.

Copy of a letter addressed by the Chief Clerk of the General Register Office, in reply to a private medical practitioner, who had intimated that the profession would decline to give the required certificate:

"General Register Office, Oct. 6th, 1853.

"SIR,—I am directed by the Registrar-General to acknowledge the receipt of your letter of the 4th inst., in reference to the duties imposed upon the medical profession under the provisions of the Compulsory Vaccination Act of 16th and 17th Vict., c. 100.

"In reply to your remarks upon this subject, I beg you, in the first place, distinctly to understand that, in furnishing medical practitioners throughout the kingdom with vaccination books and forms, as directed by the eleventh section of the statute, the Registrar-General has had to perform a purely ministerial duty; and that, in his official capacity, he is not required to express any opinion as to the legal obligation of medical men in private practice to perform gratuitously the duties imposed upon them. At the same time, he has no objection to state, for your information, and that of other medical men, that, according to his reading of the act, the remuneration provided by the sixth section is payable only to those medical officers and practitioners who may hold vaccination contracts (see clause 1); and that, therefore, medical men who, in the course of private practice, undertake the vaccination of children, must (unless they do it gratuitously) necessarily look for payment to the persons who employ them. Should they, however, altogether refuse to vaccinate, the Registrar-General apprehends that this result must follow; namely, that the parents will in all such cases be driven to adopt the only course then open to them, that of taking their children to be operated upon by the public vaccinator; for the act is unquestionably binding upon the parent of every child born in England after the 1st of August last (section 2); and those parents who, after having received notices from the Registrar according to section 9, shall neglect to have their children vaccinated, either by their own medical attendant or by the public vaccinator, will incur the penalty of 20s. imposed by that clause.

"The Registrar-General considers moreover that, under the act, it is the bounden duty of every medical practitioner who, in the course of private practice, performs successfully the operation of vaccination upon any child, to deliver a certificate thereof to the parent or person in charge of the child, and a duplicate of it to the Registrar; and that, if he neglect or refuse to do so, although he will not incur a pecuniary penalty, he will render himself liable to an indictment for misdemeanour; it being a well recognised rule of law, 'that, if a statute enjoin an act to be done, without pointing out any mode of punishment [for non-compliance], an indictment will lie for disobeying the injunction of the legislature.'

"I have the honour to remain, sir, your obedient servant,
(Signed) "THOMAS MANN,
"Chief Clerk."

On reading this letter in one of the journals, I immediately addressed an inquiry to the Registrar-General, in the following words:

"TO THE REGISTRAR-GENERAL.

"Alford, Lincolnshire, Oct. 20, 1853.

"SIR,—I have just read with some dismay a copy of a letter addressed from your office to a private medical practitioner, stating that, if medical men refuse to give gratuitously to the registrars duplicate certificates of vaccination in the case of private patients, they will be 'liable to an indictment for a misdemeanour'. Your letter also states that medical men who are not contracted with 'must (unless they do it gratuitously) look for payment to the persons who employ them'.

"Exactly so. And we are all, I conceive, perfectly contented to do this. But do these private patients who employ us to vaccinate their children, employ us also to give these certificates to the registrars? Certainly not. We are employed by the government to give them: and I wish to ask you most respectfully, whether, applying your own rule to the transaction, we are not entitled in this case also 'to look for payment to those who employ us', namely, to the government?

"I have the honour to be, sir,

"Your most obedient servant,

"R. U. WEST."

To this letter I received, by return of post, the following answer:

"General Register Office, Oct. 21, 1853.

"SIR,—In reply to your letter of 20th inst., I am directed by the Registrar-General to inform you that the fourth section of the Compulsory Vaccination Act imposes a duty upon the medical profession, for the performance of which, he is of opinion, they have no legal claim upon the 'government' for payment.

"I am, sir, your obedient servant,

"THOMAS MANN,

"Chief Clerk."

"R. U. WEST, Esq., Alford."

Now, this letter of the Chief Clerk fails entirely to convince me that we have no claim for payment on the government which "employs" us to give these certificates. Nay, I am pretty sure he is himself conscious that we have; for, in his letter, I find he was about to write "they have no claim", and then, as if another idea had struck him, he altered the half-written word "claim" into "legal", and wrote "claim" after it. He feels, no doubt, that we have a moral claim, and he only thinks ("he is of opinion") that we have not a legal one.

May I respectfully suggest to the profession, that we should try this question with the government? It may be done in this way. We may vaccinate, and give the certificate to the parent for his protection; and then, when the registrar applies for the duplicate, offer it to him on his payment of a small fee, say eighteen-pence, and refuse absolutely to give it without. Surely this most artful and disgraceful attempt to make us work for nothing may be defeated in some way. A licensed victualler is liable to penalties if he refuse to entertain a guest; but he can demand payment. The fact is, we have submitted quietly to this system of giving gratuitously all sorts of certificates and other helps to the registrars, until it is now attempted to "impose" upon us this gigantic scheme, by which we are to be compelled to work for nothing for the good of the public at large. "Impose" is the right word; it is an imposition, and a contemptible dodge.

I am, etc,

R. U. WEST.

Alford, Lincolnshire, Oct. 22nd, 1853.

THE VACCINATION ACT.

LETTER FROM JOHN C. BLOXAM, ESQ., TO THE EDITOR.

SIR,—The provisions of the new Vaccination Act seem to me to be intolerably oppressive. I should easily make up my mind to discontinue vaccinating, if I had only to consider the direct loss to myself; but this would, of course, be at the same time annoying to others, and also, indirectly, extensively injurious to myself. I feel inclined at present to put the government books in the fire, and vaccinate whenever desired to do so, with the understanding that I shall give no certificates; and I must then submit to the penalty, as often as it shall be imposed upon me, for contravening the terms of the act. The party vaccinated may, at any time after the vaccination, be exhibited to the public vaccinator, from whom the necessary certificates may be obtained. It may be said, perhaps, that this would be making a sacrifice without any attendant benefit; and this must be the case, I think, with any course of action that is not adopted by the leading members of the profession, and more particularly those practising in the metropolis.* No alteration will ever be made in the act, unless other parties feel the inconvenience of it as well as the medical profession.

May not, however, this grievance have resulted from our own negligence? I fancy few surgeons have been in the habit of making any returns to the National Vaccine Institution, as to the results of using the matter sent thence. I must plead guilty myself; and I do not believe any one in this neighbourhood ever makes such returns. I think, however, if the request for information had been more definite, instead of being expressed in such general terms, it would have been more attended to. I

* The pecuniary interests of the leading members of the profession in London are not involved. EDITOR.

had myself no unwillingness to report, and sometimes kept notes for the purpose; but I never knew when the "results" were complete; and, in the end, I sometimes lost, and sometimes forgot my notes.

The impression upon my mind is, that such an oppressive interference in the private business of private individuals has never been attempted to be enforced since the year 1688, as the New Vaccination Act.

I am, etc.,
JOHN C. BLOXAM.

Newport, Isle of Wight, Oct. 14th, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—Has this question occurred to your mind:—If children "are incapable of receiving the vaccine disease", does the act forbid the operator from then charging for a certificate? (Section 7.) I rather think not.

Again:—Will the new code of prices apply to all vaccinated after this date, no matter what their age? The act says, "For the vaccination of persons" (sect. 6).

I am, etc.,
A VACCINATOR.

October 10th, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—As a member of the ASSOCIATION, and a private practitioner, I should feel obliged by your answering me a few questions touching this odious, imperfect, and blundering Vaccination Bill, which will, I feel perfectly assured, give general dissatisfaction to all parties, medical and non-medical.

My first question is, Who is to remunerate the vaccinators for that class of patients who have hitherto paid them from five shillings to a guinea for the operation?—the Poor Law Board, or the patients themselves, or both?

The second question is, Is it necessary that a legal general practitioner should place after his name his titles, or will it be sufficient to sign himself surgeon, etc., as has been the custom in all cases where a certificate has been required?

An answer to these queries will greatly oblige.

I am, etc., A CONSTANT READER.

October 14th, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—The general dissatisfaction on the part of the profession at large, which has been manifested with reference to the new Vaccination Act, naturally prompts to the adoption of any modes of procedure whereby the "powers that be" might be made to estimate duly the state of opinion on the subject. I should suggest the refusal, on the part of the profession, to fill up the duplicate certificate, ordered to be sent to the registrar, whilst the parents of the child are furnished with the one which the law requires. The only question as to the practicability of this plan, comprises the desirableness of subjecting one's private patients to the intrusions of the registrar, and to the trouble of substantiating the legal vaccination of their child. This objection being removed, or void, the measure would have its due effect in impressing upon the legislature the legitimate claims of the medical profession, and their due recognition, in case of an amendment of the present ill-contrived enactment.

I am, etc., M. B.

October 22nd, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—In common, I suppose, with all my professional brethren, I have received a copy of the new Vaccination Act, and four books of forms of certificates requisite for carrying it into effect.

The act fixes the fee of the public vaccinator, who will, I presume, in most, if not all cases, be the union surgeon of the district, at one shilling and sixpence for each case within two miles of his residence, and at two shillings and sixpence if more than two miles. Fees are also to be paid to the registrar of one shilling "for searching the registry", of "sixpence for each certificate" he may grant (clause 8), and of "three pence for each child vaccinated" (clause 10); but I have looked in vain for any

fee to be paid to the private practitioner for filling up, in all ordinary cases, two certificates; and when the child is not in a fit state for vaccination within the prescribed period, three, four, or it may be half a dozen, or even more! On the contrary, clause 5 enacts that "he shall immediately deliver, without fee or reward", a certificate, etc.; and in clause 4 it is very coolly ordered that "he shall transmit a duplicate of said certificate to the registrar". In other words, he shall send his servant to the nearest post-office, in many cases half a mile or more, three or four times a week.

During the time when the bill was before Parliament, your readers will remember that petitions were presented from various branches of the Provincial Association, containing, among other allegations, complaints that, though it would throw a considerable amount of additional labour on the private practitioner, it made no provision for his remuneration. These petitions were, as might be expected, entirely disregarded; for it seems to be a settled principle in legislation, where the profession is concerned, that its claims should never be attended to—a natural result of our inattention to our own interests, and a proper reward for our readiness on all occasions to give our gratuitous services.

An obvious mode of dealing with the unjust and unreasonable requirements of the act would be simply to return the books "to the place whence they came". As the parents, however, are liable to prosecution and penalties under the act for not possessing a certificate, I purpose, as a protection to them, to give the certificates and schedules A, B, and D, to the parents, but to withhold the one schedule A, which is directed to be delivered to the registrar, till I am paid in each case a fee of one shilling. And I am glad to find that a number of my professional friends, impressed like myself with the extreme injustice of requiring us to make a sacrifice of time and trouble of no small amount without any remuneration, are quite disposed to follow my example. I am not lawyer enough to know whether, by so doing, the law would regard us as contravening the statute, and hence render us liable to proceedings for a misdemeanour; but perhaps you, Mr. Editor, or some of your intelligent correspondents, will have the goodness to enlighten me on this point.

In your last number, there are some very judicious remarks by "A Private Practitioner" on the effect which the act will have in compelling us to draw our supplies of vaccine virus from deteriorated and unhealthy sources, which I commend to the serious consideration of your readers. We may add to what he has so ably pointed out, the disadvantages under which the public vaccinator must necessarily lie, from his ignorance of the habits and history of the parents of the children from whom he takes fresh lymph. It is not possible for any man, however great his natural sagacity, however delicate his tact and discrimination, and however sincere his conscientiousness and anxiety to do right, to escape falling into errors which would be easily avoided by the ordinary medical attendant, conversant as he would be with all that he required to know. With our present pathological opinions of scrofula and syphilis, for instance, more especially on their mode of propagation through the secretions, who, be his care what it may, if he be unacquainted with the mother's history (which the public vaccinator must be in a great majority of cases), can have any security that he is not conveying the poison of one or both these diseases to a healthy child? I conceive that during lactation especially this risk is imminent; and in nine cases out of ten the operation will be performed while the child is at the mother's breast.

Your correspondent also points out a plan by which justice might have been done to all parties. "It was this: to furnish every duly qualified medical practitioner with a case-book; to require him to make quarterly returns to the guardians of each district; and that the guardians should pay each and every practitioner furnishing such returns." Nothing could be more simple, nothing more just in a remunerative sense; and nothing could be more effectual in obviating the danger of unhealthy vaccination.

With this clear appreciation of the evils which must inevitably result if the law remain as it is, and with so effectual a remedy for those evils, patent and easy of application, will the profession tamely submit to be made the instruments for carrying out the provisions of this most iniquitous law? Why can we not once meet in every city, town, and village, and send a memorial to the noble Home Secretary, who, I think, will be particularly dislike to see rescinded the blundering

year, as you have so well designated it.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—The clerk of — Union having required the qualifications of the medical men of this district (under the new Vaccination Act), one has returned himself as a M.R.C.S., and in practice before 1815. On referring to his register, I find he was baptised in June 1797; presuming him to have been only 18. Is he intitled to the double qualification?

I am, etc., R. R.

[He is as much entitled as others in the same position. The Registration recently accomplished for the purposes of the Vaccination Act, presents many fallacies. In some towns the general practitioners return themselves as consulting surgeons, whereas others in similar practice in other places call themselves "accoucheurs", or "surgeon-accoucheurs", or "physician-accoucheurs", or simply "surgeons". From this, it appears that one of the columns might with advantage be suppressed. EDITOR.]

THE VACCINATION ACT.

LETTER FROM HENRY TERRY, JUN., ESQ., TO THE EDITOR.

SIR,—It seems to me that the sentiments expressed in your leading article of the 7th instant, and also in the letters of two correspondents in the same number, on the subject of the Vaccination Bill and its effects on private practice, are somewhat overdrawn. The chief fault in my mind is that of requiring medical men to give the various certificates there mentioned "without fee or reward". I do not see anything in the act to warrant me as an union surgeon and vaccinator to interfere with the private patients of another medical man, or *vice versa*—indeed, the very first clause states that the act is "for the purpose of affording increased facilities for the vaccination of the poor"; and although the same clause provides that due notice is to be given of the times and places when the medical officer is to attend and "vaccinate all persons who may attend there", I do not think this is intended to apply to the children of the rich, and certainly it does not seem probable that patients in the higher classes of life would at all relish the idea of attending at the "place" named (however "convenient" it may be), and mix with the motley groups generally assembled on such occasions. I know not if the fact is generally known, but, I believe, under the *old act*, and therefore, perhaps, equally under the new one, all persons had a right, if they chose to avail themselves of it, to gratuitous vaccination; but, as far as my experience goes, this "slice off the general practitioner's loaf" which the "parish doctor" enjoyed was so small as not to be worthy of consideration. I believe that a certain number of parents who were unable to pay the fee to private practitioners, and, perhaps, too proud to come to the parish for anything, have taken their children to druggists and other unqualified persons for vaccination, and that vaccination has thus suffered from the inefficient manner in which it has been performed. This will obviously be prevented under the new act. One of your correspondents speaks of a "bad feeling" as likely to be "engendered between the union surgeon and private practitioner". I really cannot see at present any cause for such a presumption; neither do I think his argument against the bill is much improved by the old story of a "public vaccinator (*an union surgeon, of course*) employing some unprofessional person to act for him, and giving him threepence per case for his trouble". The case is said to have taken place "a few years back"; and I think the experience of most union surgeons of the present day will say that boards of guardians look rather too strictly after their medical officers to allow of such a proceeding.

Your correspondent H. P. quotes the case of an appointed vaccinator in his village who has "no fixed place for vaccination, except his own residence; neither are any days appointed". This, I think, shows the necessity for "compulsory vaccination", as, in all probability, there existed some absurd prejudices amongst the poor, which the vaccinator had either no time or inclination to conquer. I myself know a gentleman who resorts to the expedient of tempting the children in his district to be vaccinated by parading the village with a handful of *sweetmeats*, which proves generally successful. In most unions, it has been customary to appoint certain places and days for vaccinating the poor; but in my own case, and perhaps in others, this was seldom carried into effect, as it was impossible always to ensure a supply of *fresh lymph* at the proper time;

and, to vaccinate any number of children at one time, it is practically necessary to secure two or three healthy children at the eighth day of vaccination.

In conclusion, I would express an opinion that both classes of medical men will be benefited by the act: the *private practitioner*, because, from various reasons, the necessity of pressing on his patients the importance of vaccination will now be needless; and the *union surgeon*, because all the children of paupers, *i. e.*, those who are unable to pay for medical advice, will come under his notice more thoroughly than they did before.

On the question of the *bad feeling* likely to be engendered between private practitioners and union surgeons, I believe this has always existed to a certain extent, and possibly always will, independently of the Vaccination Act; but I do not see that the union surgeon is necessarily to be blamed for this. Perhaps a circumstance that occurred to two friends of mine may strengthen this opinion. A surgeon was attending some important case of long standing, during which time the friends in their anxiety requested a consultation with Mr. —, the union surgeon. What was the reply? "You must have some one else. I had rather not meet Mr. —; he is only the parish doctor!" This I know to be the fact, as I have the anecdote from both medical men, who, as I said before, are friends of mine. I am, etc.,

HENRY TERRY, JUN.

Northampton, October 10th, 1853.

THE VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—I take the liberty of craving a small space in your Journal for briefly replying to the uncalled for as well as unjust remarks against Union Surgeons, by "A Private Practitioner", in last week's Journal. I quite agree with your correspondent that the Vaccination Extension Act is a monster injustice to the profession, as well to union surgeons as to private practitioners; unless "A Private Practitioner" considers 1s. 6d. per successful case ample remuneration for a *Parish Doctor*. I would ask "A Private Practitioner", Has he not heretofore, as well as other private practitioners, vaccinated numbers gratuitously, although it was not done to prevent the parish doctor from interfering with his or their patients, but simply because there are and ever will be a class of patients who pay for their confinements fifteen shillings or a guinea, and whose child is vaccinated into the bargain. What loss can "A Private Practitioner" now sustain by the same practice? unless, perhaps, he attends none but the middle or upper classes of patients, who will still pay as before for vaccination; or, at least, "A Private Practitioner" will charge it in his bill if he is not a greater fool than I take him to be. So much for the injustice of the Act to private practitioners in general, and "A Private Practitioner" in particular.

Under this Act, there is less necessity for *parish doctors* interfering with private practitioners' patients (if indeed they ever did so) than before; as instead of the surgeon calling at the houses of patients, the latter *must* call at the place and time appointed by the former, notice of which time and place will be given, as well as warning by the registrar of the district. So much for the *parish doctor's* intrusion.

The final statement of "A Private Practitioner" is so untenable by facts, that I shall not trouble myself with a refutation. I would merely ask "A Private Practitioner", From what class does he supply his middle and upper class of patients, who from scrofula or some other constitutional taint, are unable to nurse their equally scrofulous offspring without nurses? I would likewise ask him, Does he keep a cow on his premises to supply the same class of patients with genuine vaccine lymph.

Had the even handed justice been carried out which "A Private Practitioner" says might have been followed—*viz.*, that of furnishing a case book to each practitioner (private I presume) so that he might make quarterly returns of the numbers vaccinated, and of course draw the amount in cash, we should not have had the pleasure of perusing his insolent tirade against union surgeons. I greatly fear "A Private Practitioner" has been a defeated candidate for union or vaccination honours, and hence the attempt to malign parish doctors.

I, sir, have had the honour of holding a union appointment for the last four years, and also that of vaccinator of the district; and I know hundreds holding similar appointments. I assert without fear of contradiction even from "A Private Practitioner", that amongst our ranks are to be found men of the highest professional attainments, honour, and integrity, and who would spurn

the mean acts which "A Private Practitioner" attributes to us, even before an opportunity has been afforded to us of so acting (if capable). For, remember, although the Act is in force, it has not yet been acted upon. In conclusion, I would say to "A Private Practitioner" as our Saviour said to the Pharisees of old, "First cast out the beam out of thine own eye; and then shalt thou see clearly to cast out the mote out of thy brother's eye".

I am, etc.,

A UNION SURGEON AND A PRIVATE PRACTITIONER.

October 10th, 1853.

EVILS OF THE VACCINATION ACT MUST BE ALLOWED TO WORK THEIR OWN CURE.

LETTER TO THE EDITOR.

SIR,—In regard to the Vaccination Act, nothing now remains to be done but to let those who have been so torpid of late feel the inconvenience of the act: that may, *perhaps*, arouse them. But I fear a vast number of the union vaccinators are well pleased with the slight addition to the miserable stipend for so important a duty. I have no patience with them, and no hope of them, and little for the profession at present. Lord Palmerston has completely deceived and betrayed us. I am, etc.,

R. C.

October 10th, 1853.

THE NEW VACCINATION ACT.

LETTER TO THE EDITOR.

SIR,—A deep sense of the great injustice done to me individually, and to the profession generally, by the new Act, prompts me to let you know what I have personally seen of its working here. I live in a large city which is divided for vaccination purposes into four or five districts, each having its publicly appointed and publicly paid vaccinator. Immediately the Act came into operation, I was surprised to find the walls in every direction covered with large placards having the names of these vaccinators in conspicuous characters, together with their addresses. They purported to have been issued by public authority of the parochial body of the city, informing every citizen that the law now required every child to be vaccinated; that *all* might avail themselves of the perfectly gratuitous services of the public vaccinators, who would vaccinate the children of *all classes*, either at the public places appointed for that purpose, or at any reasonable time at the private residences of these gentlemen. Now, what is the effect upon the private practitioner? It will inevitably make him vaccinate without any fee in nearly all cases, and be obliged moreover to give certificates for each case "without fee or reward". The case was hard enough before the new act came into operation. I have, years back, been able to earn a few fees by vaccination; but now nearly all ask whether I charge anything for vaccination, as their neighbours have been to Mr. So-and-so, the public vaccinator, who kindly did it for nothing; so, not to lose my patient, I also do the same. Now this has occurred not only amongst the poor and the needy, but amongst those who could well afford to pay a fee. Thus a patient of mine, who pays £200 per annum for the rent of his shop, used to pay his 10s. fee for the vaccination of his child; but the last time I could get nothing, and all this when our poor rates are increased to pay those who vaccinate gratuitously. In plain words, we are obliged, under pain of fine and imprisonment, to pay poor rates, which go with the national rates, including the iniquitous income-tax, to enable our professional and privileged neighbours to take away our patients or at least a fee we should otherwise fairly have earned. I hesitate not to say, that the new Act is a most unmitigated blunder in legislation. Whether intended or not to be so, in practice it induces spoliation and monopoly. A medical man's time is his bread, and no power has ever been delegated to the State to demand services from anyone without a corresponding reward or privilege. What are our politicians about? Here we have an act in operation, which, so far as medical services are concerned, is essentially *communitistic*. A rate is raised from all, including medical men, for the purpose of doing something for all *gratuitously*; and to enable a few of our number to deprive us of our former fees and a risk of taking away our patients and family connexions; whilst the private practitioner is obliged to do this for nothing and also to give certificates in each case, which must be "without fee or reward".

Now I have to vaccinate nearly all my private patients' children gratuitously, or nearly so; I also find it necessary to vaccinate numbers of other poor patients' children who wish me

to vaccinate them, and in all these cases I am obliged to give certificates without "fee or reward".

But, what are we to do? Let us never cease to protest against this measure of *spoliation and communism*; we must act unitedly and petition Parliament immediately it meets upon the subject. But what I deem of far more importance, let us *individually* petition the legislature. Thousands of these petitions sent, must and will tell upon the House of Commons and upon public opinion. Each person has an undoubted right to petition the House upon any subject by which he deems himself aggrieved. I shall, as soon as the House sits, forward my own individual petition to the leading member of our city; now, if all my injured brethren of the profession will only, each in his case, act in a similar way, there can be no doubt of the issue. An Englishman's sense of fair play will never allow this act to go unrepealed, and which could never have passed had it not been unfairly hurried through Parliament. What are we to petition for? Perhaps, all things considered, a compulsory Vaccination Act will be advisable; the State has an undoubted right to say, this child must be vaccinated by a regularly qualified practitioner; but free trade and fair play says it shall not do so by paying certain monopolists to do that for all who choose to accept gratuitous services. Let pauper children, *i.e.*, the children of persons receiving parochial relief, be vaccinated at the expense of the parish; and perhaps other poor children, by the parents bringing a certificate from two householders to the effect that the parents are too poor to pay any fee for vaccination. Thus we should get rid of the scourge of the small-pox, without at the same time victimising the majority of the members of that profession of which Jenner was a bright ornament in giving to the world his never to be forgotten discovery. I am, etc.,

ADEPT.

CHOLERA.

LETTER TO THE EDITOR.

SIR,—When you take it into your editorial consideration to review the swarm of choleraic literature which now infests our professional atmosphere, permit me to suggest the following as an appropriate heading for your article:

"Ambubiarum collegia, pharmacopole,
Mendici, mime, balatrone; hoc genus omne."

Of such are the popular writers on cholera.

The advent of an unmanageable epidemic is generally made an excuse for the publication of all sorts of crude and ill considered notions from the pen of the sciolist; it is not enough that we have to wade through ponderous blue books and the authoritative documents of our superiors and elders, but our little great men pour in upon us the ephemeral spawn of their brains, in the shape of *Cholera for Sixpence*; *Thoughts for a Shilling*; *Cholera and all Epidemics nothing more or less than Galvanic Batteries*. By M. B., F. O. O. L., etc. Also, by the same author, *Cholera treated by Vulcanised India Rubber and Small Doses of Chatnee Sauce*. Now, sir, if, instead of troubling our heads about the treatment, concerning which the wisest among us are not agreed, we address ourselves to the prevention of this disease, much good, I am persuaded, may be done: but then comes the question—*What is cholera?*

All sanitary measures appear to be based on the zymotic theory of cholera. There are to be found in the voluminous reports which have been officially issued, and elsewhere, many striking and sensible passages in support of this doctrine: indeed, it seems to be the only one at present capable of answering the searching questions which are every day put to us. I am not acquainted with any writer who has given so accurate a definition of the zymotic theory as Dr. Carpenter. This distinguished physiologist has gone deeply into the matter; and with great logical acumen has advanced far towards establishing the immutable truth of the hypothesis. At present, I have no intention of meddling with the theory in question further than to show that in order to prevent cholera, we must realise in our own minds a correct idea of its cause. To adopt, then, Dr. Carpenter's own words, we may say that the cause of cholera is "a certain general condition of the human body *plus* the specific poison." These two being the unconditional and variable antecedents, or, in other words, the sum of the necessary conditions, being included in these antecedents, they *must* be considered the cause. Now, it is well known that contingencies are absolutely required to produce the disease cannot be developed when one is present, and then whether the same law of causation holds in other diseases, and if so, whether we can make clearer by an illustration.

What is the cause of hydrophobia? Do we not here also observe two antecedents; namely, a person to be bitten, and a mad dog to bite; the latter representing the specific poison? Now, how has Government dealt with hydrophobia, so as to remove one of the antecedents, and therefore the cause? I think, wisely. The Government could not remove the first antecedent by shutting up the people during the dog days, and therefore it took cognizance of the second, and put the dogs into quarantine. The result is, that hydrophobia from having been a disease of frequent occurrence in London, has become exceedingly rare. And now, what is the case with cholera? Can we shut up the specific poison of cholera, as we do the dogs? I fear not: the quarantine laws have hitherto been inadequate to keep the enemy at bay: but, fortunately, we have considerable command over the other antecedent, the "certain general condition of the human body"; for it has been found that by taking care to prevent the accumulation of disintegrated azotized material within the system, the leaven of the disease finds no appropriate pabulum to maintain its existence.

I believe, sir, that all comprehensive and rational schemes for the prevention of cholera must be founded on the principles which Dr. Carpenter has laid down; and I now quit the subject with an urgent recommendation to your readers to make themselves acquainted with the doctrines of the zymotic theory, as that learned physiologist has explained it in the *Med. Chir. Review* for January 1853.

I am, etc., COSMOPOLITE.

October 1853.

CHOLERA.

LETTER FROM J. PAXTON, M.D., TO THE EDITOR.

SIR,—The cholera, like many other evils of this life, has a reaction tending to work out some important beneficial results, so that ultimately we learn wisdom from the things we suffer. Thus inestimable benefits will follow those sanitary measures which are being carried out, and which probably would not have been thought of had the cholera not appeared in our towns. And yet cleanliness, wholesome nourishment, and abundance of fresh air and good water, are no less essentially protective against epidemics and many other diseases which are fatal, or, at least, keep the health below par.

Without intending to compliment any one, let me observe that the detection of certain deadly agents which have surrounded us, and of which we were formerly unconscious, has been owing to the progress of the physical sciences. The exhortations given to the boards of guardians and other public bodies, on the necessity of the removal of deadly agents for the wellbeing of all classes, is mainly owing to the labours and penetration of scientific medical men. We acknowledge that very much is due to the echo of the daily papers for the impressive and often brilliant articles on public hygiene. Without the aid of the *Times* and other journals, all the medical exposures and warnings would avail but little with people in general. Your last leading articles, the republication of the circular of the College of Physicians, and the *questions* of the Council of the Association, are excellent, and calculated to bring the subject of cholera very systematically under the serious consideration of the profession. Still, however, more is required. The records of ten thousand cases, and charts of the course it has pursued, drawn out with the most accurate details, might illustrate the natural history of the epidemic, but it would give no clear insight into the real character of the disease. We require pathological memoranda to be collected by those who are quite competent to the task, who would be willing to undertake a more than statistical and medical description of the disease. We require an extended investigation of the more intimate changes which the organisms of the human frame undergo stage by stage while the choleraic struggles last, and the conditions an inspection exhibits when the struggle is ended.

I now come to a consideration of the point I am aiming at; viz., whether it is not desirable that a PATHOLOGICAL COMMISSION should be appointed, under the General Board of Health, for the further investigation of the morbid phenomena of cholera; that two or more of the commissioners be sent into the district where there may be an outbreak of the disease, there (without interfering in the management of the cases) to examine and report on all circumstances specially relating to organic changes produced in the subjects of cholera? Such inquiry should particularly embrace a most critical view of *post mortem* anatomical appearances.

Thus, assuming cholera to be a disease of the blood, they should note: 1, the colour in the arteries and veins; 2, the specific gravity;

3, per centage of serum and crassamentum; 4, solid contents; 5, measurement of red and white corpuscles, their relative proportion, and any departure from their normal forms; 6, proportion of water; 7, albumen; 8, fibrin; 9, extractive matters; 10, chloride of sodium; 11, carbonate of sodium; 12, chloride of potassium; 13, phosphate of lime; 14, phosphate of soda; 15, phosphate of magnesia; 16, lactate of soda; 17, lactate of ammonia; 18, protoxide of iron; 19, phosphate of iron; 20, any addition of foreign substances, or any abstraction of normal substances from the blood. To these points may be added the examination of the contents of the thoracic duct and receptaculum chyli, the liquor chyli, and its globules, in order to ascertain any deficiencies, increase, or other deviations from health in the preparatory materials of the blood.

I need not say, that the noting of these items forms only part of the duty of the observer. The chemical and microscopical states of fluids ejected from the stomach and bowels might be regarded as deserving equal attention.

I am, etc.,

J. PAXTON.

Rugby, October, 1853.

[The *post mortem* anatomical appearances in cholera have been ably described by Dr. W. G. Gairdner, of Edinburgh, and also by Dr. Raikem, and by M.M. Lévy and Tholozan. An account of these researches is given in the *London Journal of Medicine* for 1840.—EDITOR.]

CHOLERA.

LETTER FROM E. GREENHOW, M.D., TO THE EDITOR.

SIR,—Asiatic cholera having again visited our shores, it may not be uninteresting to some of your readers to hear the reminiscences of those who on former occasions have been actively engaged in its treatment, and although little progress has been made in elucidating its nature or in effecting its cure, still something may be gleaned from the experience of others.

It is now generally admitted that heroic remedies are not such as are calculated to be useful in the treatment of cholera; and it is only by the steady perseverance of mild treatment of such a nature as is likely to obviate the symptoms of the disease that good can be accomplished. How far the suspension of the functions of the liver and kidneys are concerned in the production of the disease, we cannot tell, although the non-excretion of the substances eliminated by these organs from the blood may have much to do in producing some of the symptoms; and in treating the disease, the restoring these functions should not be lost sight of.

It is with some diffidence that I now bring forward the plan I pursued during the last visitation of cholera, because it was adopted after the disease had prevailed some time; and it is well known that towards the close of an epidemic there is a greater tendency to recovery than at its commencement. Nevertheless, had my infirm state of health not now prevented me from personally engaging in its treatment, I should most undoubtedly have pursued the same plan in preference to all others. The medicine, remedy I dare not call it, is the following,

R Pulv. hyd. cum cretâ, et pulv. ipecac. comp., aa gr. i.
Conf. rosæ q. s. ut fiat pil.

These pills are equally applicable both to diarrhœa and to cholera. In case of diarrhœa the patient may take one pill every half hour if the case is urgent, at the same time keeping warm and quiet, or what is better still, keeping in bed; the diet should consist of sago, or arrowroot and brandy; tea also may be taken. Where cholera has decidedly supervened, one pill should be taken every ten minutes or quarter of an hour, and no other medicine should be administered. The first indication of reaction is apparent in the skin, which has hitherto been bathed in a cold acetic moisture, which now changes its character, assuming a warm natural feeling, and this often occurs before the pulse is distinct at the wrist.

I am, etc.,

EDWARD GREENHOW, M.D., F.R.C.P. Edin.

Fulford, York, Sept. 15th, 1853.

MEDICAL ETHICS: THE PROFESSION IN THE COLONIES.

LETTER TO THE EDITOR FROM THOMAS NICHOLSON, M.D., OF ANTIGUA.

SIR,—I am glad to see it announced in the ASSOCIATION JOURNAL for July 29th, that Mr. Michael intends to move, at the annual meeting of the Association at Swansea, "That, in the opinion of the meeting, it is desirable that a code of laws,

for the guidance of the members in all matters appertaining to professional ethics, should be adopted;" etc. No respectable member of the profession can have any doubt of the desirableness of this resolution; and, therefore, it is to be hoped that it will meet with unanimous support. The Medical Reform Bill proposed to be enacted by Parliament may protect the profession and the public from the practices of unqualified pretenders; but how are we to be protected from the practice of quackery by the unprincipled but qualified members of the profession? This, I take it, must be done by the profession itself; and, if all the licensing bodies would lay aside their jealousies, and enter into combination for this very desirable end, it might be very easily accomplished. Let every licensing body publish annually an alphabetical list of its members, with their place of residence; and when any of these has been convicted of dishonourable conduct, or a breach of the laws of medical ethics, let his name be struck off the list for one or more years, according to the degree or enormity of his offence. Some measure of this kind will be found to be a necessary adjunct to any reform bill that contemplates the support of the dignity and respectability of the medical profession.

We have in this colony a very simple law for regulating the practice of physic, which, although it was passed so far back as 1812, might be advantageously imitated by the Imperial Parliament.

No one is permitted, under a penalty of two hundred pounds currency, to practise medicine or surgery without a license from the Governor, or person administering the government. The Governor is not authorised to grant such a license to any one who cannot produce a diploma from certain universities and colleges named in the act, or a certificate of his qualification from a Board of Examiners in this colony. The examiners are the three senior medical practitioners, or, in case of their inability to attend, any other medical practitioners whom the Governor may appoint; and these examiners take an oath, in the presence of the candidate, to act justly and conscientiously, without favour or affection.

The universities specified in the act are Oxford, Cambridge, Edinburgh, Glasgow, and Dublin, and the Royal College of Surgeons of London. In 1822, the Royal College of Surgeons of Edinburgh was added, and, by a subsequent act, the recognition was extended to all the corporate bodies in Great Britain and Ireland who are legally authorised to grant diplomas in medicine and surgery; but, for some reason or other, the Royal assent was not given to this last bill.

This act has been found to work well, so far as it protects the community from unqualified practitioners; and, until recently, the greatest harmony prevailed amongst the members of the profession: and, notwithstanding the limited field of practice, and the small number of her population, Antigua records in her history the names of many medical men who were ornaments to society as well as their profession. Whatever their university distinctions may have been, it was at first necessary, and is even now customary, for every one to practise as a general practitioner, and dispense his own prescriptions; and, whenever the circumstances of the patient could afford the expense, consultations were held without exciting the slightest jealousy or ill feeling.

In 1843, all the medical men then engaged in practice formed themselves into an association for protecting the interests and respectability of the profession, and promoting unanimity and kindly feelings towards each other. But, alas! of twelve who assembled for this purpose on the 18th November of that year, in the prime of life, seven have gone to their eternal rest! Such is the wear and tear of life in tropical practice.

One of the first subjects which was forced upon the attention of the society, by the change in our social system, was the regulation of the rate of remuneration. The legislature, to encourage habits of steady and continuous labour amongst the newly emancipated, had very wisely made it imperative on the employer to provide medical attendance for his contract labourer, such as he had been accustomed to in the time of slavery; but many of the proprietors, particularly some who had formed their notions of the value of medical services at the Poor-law Board in England, were disposed to reduce the remuneration to a degree which was derogatory to the respectability, and would have threatened the annihilation, of the profession in the colony. To protect themselves from this attempt required the united efforts of the association.

The mode of charging in private practice likewise underwent revision. The old system of including remuneration for advice and attendance in the charge for medicines was very properly abolished, and a table of fees established, in which a charge for

visits, not exceeding two in the same day, was agreed upon; and the price of medicines dispensed was reduced to their real value. Together with these equitable changes, the fees for operations in surgery and midwifery were also in many cases reduced; nevertheless, great dissatisfaction was excited in the community, and murmurs were heard of threats to introduce other medical men. At this time, we had imported an assistant from England, who was bound by a contract entered into in London to serve us for three years, and likewise not to practise in Antigua without our permission. He had not been more than five weeks in our service when he refused to fulfil his engagement, and denied the validity of the instrument by which he had bound himself, because it was not on stamped paper. He was a Graduate of Glasgow, and a Member of the College of Surgeons of England; and, from his family connexions, better things were expected of him. But *virtus est optima nobilitas*. The contract was sent to England to be stamped; an action was brought against him in the Court of Common Pleas, and a verdict in our favour to the amount of £300 currency was awarded. The agreement not to practise in Antigua without our consent was set aside, as contrary to the public interests.

In consequence of this dishonourable conduct, all the members of the Association resolved that they would hold no fellowship with him, nor recognise him as a member of the profession. On the other hand, he threatened to fill the island with his countrymen, Irish Doctors; but his brother-in-law was the only one that obeyed his invitation. Another relation soon followed, as a druggist; and by their combined energies, and the sale of Holloway's pills, soda water, and perfumery, they appear to be driving a flourishing trade.

Thus was the Medical Association virtually annihilated, the community had no sympathy with us: contracts for attendance on families, estates, and friendly societies were entered into with the recusant doctors on the most degrading terms; and all harmony and good feeling amongst the members of the profession were destroyed. But time smooths many asperities, death had been busy amongst the older members of the profession, and the reign of peace and harmony was apparently about to be re-established; when, lo and behold, these renegades, forgetting the circumstances connected with their introduction amongst us, set themselves up as the self appointed defenders of what they term the rights and privileges of the profession. Because the medical attendance on this infirmary has been for the last nine years restricted by the managers to one medical establishment, which for years had attended and supplied the patients with medicine gratuitously, one of these free trade doctors has, in a series of anonymous letters in the island newspapers, inveighed against monopolies, and attacked the medical officers with low, scurrilous abuse, most dishonourable to any member of a learned profession. But I must reserve the remainder of their history for another letter.

During the earlier periods of slavery, the charge for attendance on estates was four shillings for each slave, payable in the produce of the island: latterly, it was commuted for cash payments at 2s. 8d. a head, and 10d. each for surgery, making 3s. 6d. When the general emancipation took place, the planter was compelled by law to find medical attendance for his contract labourer only; but most of the proprietors entered into an agreement with the medical attendant to visit all that were resident on the estate, both adults and children, and two thirds of the average amount paid during slavery was generally the salary fixed upon. The duty to be performed comprised one weekly visit at least, the supply of medicines, surgery, midwifery, and attendance on the overseer.

Mr. Tollemache, a wealthy English proprietor, who admitted that he had received in an average of ten years an annual profit from his estates in Antigua of £3,073, when examined before a committee of the House of Commons, stated that during that time the doctors were *extravagantly paid*, and he reduced their salaries more than one-third. This *extravagant* payment was 2s. 6d. sterling a head, supposing that the same number resided on the estates as during slavery, and he reduced it to 1s. 7½d.!! We formerly attended two of his estates, but we would not submit to the reduction, unless that he could show us that there was a proportionate reduction in the number of persons to be attended. This was not complied with, and we gave up the attendance, but it was readily accepted by the Irish doctors.

Mr. Tollemache stated to the committee, that, if he had the power, he would abolish the contract law and discontinue medical attendance on the labourer. By this proceeding he would save, according to his own estimate of the amount, in the expense of producing each hundredweight of sugar, when he was paying the doctors *extravagantly* for their services.

The evil consequences of neglecting to make provision for the medical care of the labouring class, may be seen in the present state of Jamaica, as represented in the reports of Dr. Gavin Milroy and of the General Board of Health of that island.

In St. Kitts, also, where no contract law exists, the Board of Health, being convinced that the decrease of the labouring population is in some measure attributable to great mortality among their children, has recently recommended to the legislature the enactment of some law for providing, at the public expense, medical attendance on all children under nine years of age. To carry out any measure of this kind, a rate must be levied on the estates, and I would ask whether this or the Antigua plan is likely to be most burdensome to the planter?

In Montserrat, where the profession met with the same neglect and discouragement, there was no medical man in the island when yellow fever broke out about a month ago, and the president administering the Government died without the benefit of that science which the meanest pauper in England enjoys.

I am, etc.,

THOMAS NICHOLSON, M.D.

Antigua, Sept. 12th, 1853.

P.S. Since the above was written, I have read the debate at Swansea on Mr. Michael's motion. While I rejoice at its having been carried, I cannot help expressing my extreme disappointment at the lukewarmness with which the subject of medical ethics was received. When the battle of life has been successfully fought and the pinnacle of ambition attained, it is not kind to look down with unconcern upon the struggles of the multitude below. The Americans are taking the lead of us in medical ethics.

T.N.

Antigua, Sept. 28th, 1850.

MEDICAL ETHICS AND ASSOCIATION REFORM.

LETTER FROM H. L. SMITH, ESQ., TO THE EDITOR.

SIR,—Fully concurring in the necessity of medical reform, both as regards medical attendance on the sick poor, and the conduct of medical men towards each other, I rejoice that the "Hopeful Member" of our Association has drawn me out, and challenged me to appear before the ethical branch of the Association, for the offence of advertising periodically my attendance on the out-patients of the Southam Infirmary, at Northampton, and, he might have added, other places. I rejoice, because it will enable me in my defence before that council, to explain to them more fully (than I have hitherto had an opportunity of doing), the true principles on which they ought to act, and the economy of time and labour, with the more extensive usefulness of the profession to the working classes, in building them up into the social fabric, as they only can do. These principles, it has been my highest ambition to make general, ever since the time I had an oath imposed upon me by the Royal College of Surgeons (now upwards of forty years since); and that oath and that inquiry shall justify me, for all delinquencies irregular or defective, which our "hopeful member", or any other man, can bring against me. A passionate regard for the progress and practical application of science, an enthusiastic devotion to the welfare of man—man in the aggregate—man in the universal—the more intense, as it is manifest that his original dominion over all created things is being progressively, in this "evening of light", restored to him. These feelings should at this time be the characteristic of the medical profession; and I crave for nothing so much as the inquiry of which "Hopeful" has created the necessity. Let him supply me at once with the names of the jurors, and of the offences, medical or social, with which he has accused me, and I will meet him gladly, in no unfriendly spirit, either in London, or any of the midland county towns, as may be most convenient to the inquirer.

I am, etc., H. L. SMITH.

Southam, October 14th, 1853.

[We thank Mr. Smith for his letter. The subject of newspaper advertising by professional men well merits investigation. It is but fair to Mr. Smith, to state that his advertisements have appeared for the last thirty years in the Northampton papers; and that similar announcements are quite usual in that town. The duty of the Ethical Committee is simply to collect information and make suggestions.—EDITOR.]

MEDICAL ETHICS AND ASSOCIATION REFORM.

LETTER FROM DR. FAIRCLOTH TO THE EDITOR.

SIR,—The invidious manner in which my name appears in the ASSOCIATION JOURNAL of this day, in a letter on Medical Ethics, under the signature of "a Hopeful Member", is most

unwarrantable and most unjust. I had no choice permitted me. I simply wished to announce to my friends at a distance, that I had made an important change in my mode of practice. In the offence imputed to me, I merely followed out a custom, which is, in this town, hallowed by long usage.

I am, etc., JOHN FAIRCLOTH.

Northampton, October 14th, 1853.

[We had no right and we had no wish to impute blame to Dr. Faircloth. We did not do so. In following out a custom, he cannot with justice be censured for what might *prima facie* appear questionable.—EDITOR.]

DR. MAYNE'S LEXICON AND ITS PRICE.

LETTER FROM THE AUTHOR TO THE EDITOR.

SIR,—Having been from home since the 1st instant, in the hope of improving my state of health, I have only now seen the letter of "A Subscriber", in the JOURNAL of the 4th, directing my attention to what he considers a glaring defect in the commercial arrangements of my Expository Lexicon; namely, that the price is not less to subscribers than to ordinary purchasers; and suggesting to me to reduce the price of subscribers' copies from thirty shillings to twenty-four, or twenty-five shillings. I confess, that this suggestion fell unpleasantly on my mind, as evincing, at least in one gentleman, a non-appreciation of the toil and anxiety inseparable from the production of such a work.

I was led to adopt the mode of publishing by subscription, simply, with the view of thereby being relieved of the inconvenience of a very heavy expenditure; and I accordingly appealed to my professional brethren, under a feeling not over-presumptuous, I trust, that having laboured long to accomplish what hundreds in their first ranks have testified to be a useful and much required work, I had a claim to support. To all who have recognised that claim, by honouring me with their subscriptions, I am sincerely grateful.

On most of the subscriber's copies I already sacrifice above ten per cent., as the cost of arrangements, for its delivery, etc.; and to reduce the price to twenty-four or twenty-five shillings, would entail a total loss to me, upon these, of thirty per cent.—a benefit arising out of a subscription list, which, surely, "a subscriber" did not contemplate in his singular suggestion.

I have no controul over the present usages of the trade; neither, in fairness, may I attempt to undersell its members by the course pointed out.

Thanking "A Subscriber" for his suggestion and good wishes.

I am, etc.,

R. G. MAYNE.

Leeds, October 17th, 1853.

[As we understood the letter of "A Subscriber", no objection was raised to the plan of publishing by subscription. What was objected to was, that the price to subscribers was not less than that to non-subscribers. By charging a lower price to subscribers, an obvious advantage is gained by them; and no less advantage should be gained by the author, as there would then be no inducement for individuals to hold back from subscribing, in order that they might obtain the work at a much lower price from the publisher. We take this opportunity of expressing our high admiration of Dr. Mayne's work.—EDITOR.]

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

LETTER FROM THE REGISTRAR TO THE EDITOR.

SIR,—Permit me to call your attention to an error, evidently unintentional on your part, in the last number of the ASSOCIATION JOURNAL, XLII, p. 938, second column, in which you have named Faculty of Physicians and Surgeons of Glasgow, which should have been Faculty of Medicine of Glasgow, a modern, self constituted body; while the Faculty of Physicians and Surgeons of Glasgow, was constituted in the year 1509, by Royal Charter, ratified by an Act of the Scottish Parliament, and having the privileges of the said Faculty better regulated and defined by xiii Victoria Regiæ, cap. xx.

Please to receive (as herewith inclosed), the annual list of our registry for the past year for your use; also our office bearers names for the year from October 1st, 1853, till October 1st, 1854.

I am, etc.,

JOHN AITKEN

Registrar of Fac. of Phys. and Surg. of Glasgow.

21, Blythwood Square, Glasgow, Oct. 22nd, 1853.

NEWS AND TOPICS OF THE DAY.

[Continued from page 956.]

cover as conductors the names of Dr. Christison, Dr. Simpson, Dr. Bennett, Dr. MacLagan, Dr. Robertson, and Mr. Syme; but, with the exception of the name of Dr. Robertson, they have, for some unexplained cause, been withdrawn. It is understood that the *Monthly Journal* is to be henceforth conducted by Dr. Bennett, with the co-operation of a part of the former staff.

Some of the leading members of the profession in Edinburgh desire a fusion of parties in favour of one efficient journal; but, till the meeting of the 10th, the exact position of affairs is not likely to transpire. We wish peace and prosperity to all concerned.

MEDICAL SOCIETY OF LONDON. The following papers are announced as intended to be read at the ordinary meetings of this society.

Saturday, October 20th. Robert Barnes, M.D., "On the Treatment of Labour marked by Defective Uterine Action, and the Comparative Value of Ergot of Rye and Galvanism in Obstetric Practice."

Saturday, November 5th. J. R. Cormack, M.D., "On Cholera."

Saturday, November 12th. R. H. Semple, M.D., "On the Pathology and Treatment of Cerebral Diseases."

Monday, November 14th, in the Physiological Section. Edwards Crisp, M.D., "On the Form and Weight of the Heart, the Diameter of the Aorta, and the Size of the Blood-Corpuscles, in the various classes of Vertebrate Animals."

Saturday, November 19th. Haynes Walton, Esq., "On Inflammation of the Eye-Ball, especially that form of it usually called Iritis."

Saturday, November 26th. E. J. Tilt, M.D., "On Internal Metritis."

CHAIR OF NATURAL HISTORY IN THE UNIVERSITY OF EDINBURGH. Professor Jameson, in consequence of his advanced age and the present state of his health, has intimated to the Government his intention to resign the chair of Natural History in the University of Edinburgh, on certain conditions. The College Committee of the Town-Council consider the conditions to be very reasonable, especially when the career of the venerable professor, and the services he has rendered to science are considered, and they have urged Government to deal with the professor in the most liberal manner. The Lord Provost has accordingly transmitted a letter in support of the conditions upon which the resignation takes place. No answer has yet been received to the professor's letter, intimating his willingness to resign. The appointment of a successor lies with the Crown; but the appointment to the curatorship of the museum, which is generally united to the professorship, belongs to the Town-Council. Professor Edward Forbes, of King's College, London, is mentioned as the probable successor to Professor Jameson.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW. Office Bearers for 1853-4: Alexander Dunlop Anderson, M.D., President; Robert Gray Maxwell, Surgeon, Vice-President; Robert Hunter, M.D., Treasurer. Councillors: James Watson, M.D.; Andrew Buchanan, M.D.; William Weir, M.D. John Aitken, M.D., Registrar.

PASS LIST. Fellows admitted since Oct. 1st, 1852:—Joshua Paterson, Glasgow; William Eadie, Fifeshire; John Black Cowan, Glasgow; Edward Gylles Crooke, Leyland, Lancashire; Julius Bernhard Klingner, Portsoy, Banffshire.

LICENTIATES admitted:—Thomas McGill, Glasgow; Christopher Deighton, Scotland; Gustavus Evans, Wales; William Edward Crook, London; Thomas Eastwood, Salford; William Fleming Cullen, Scotland; Archibald Campbell, Scotland; James Wilson, Scotland; Joseph Blick Atherley, England; William Parker, Glasgow; George Husband Baird McLeod, Glasgow; Richard Cleve Heighway, England; Robert Denn Christmas, England; Andrew McIntyre, Scotland; John Silvester Wright, England; Angus McIndoe, Scotland; Alexander John Stewart, Ireland; Robert Fleetwood Andrews, Ireland; Robert Hewer, England; John Jones, Wales; John Spence, England; James George Wilson, Glasgow; Alexander Angus McDowall, Glasgow; William Graham, Glasgow; William Henry Ludlow, England; William Henry Valpy, England; Alexander Wilson Marshall, Scotland; Edmund Braithwaite, England; Paul Maylor, Cork; James Weaver, England; Samuel Paul Barnsdale, England; Samuel Russell Conolly, Ireland; Francis Bowen, Quebec, Canada; William James Sandels, Ireland.

ROYAL COLLEGE OF SURGEONS:—PASS LISTS. Members admitted at the meeting of the Court of Examiners on the 7th inst.:—Henry Chambers, South Australia; Theodore Duka, Calcutta; James Hester, Oxford; Robert Car Brackenbury Holland, Bristol; Edward Gregg Noott, Gosport; George Whitfield Sparke, North Buildings, Finsbury; John Swift Walker, Sheerness; Charles Yarwood, Birmingham.

At the same meeting of the Court, Mr. John Felix Johnson passed his examination for Naval Surgeon. This gentleman had previously been admitted a Member of the College, his diploma bearing date July 14th, 1848.

Oct. 14th:—George Augustus Fulcher, Finchley, Middlesex; James Hadaway, St. Nicholas, Isle of Thanet; James Kearney, Calcutta; Frank Powell, Chichester, Sussex; George Edmund Smale, Plymouth; St. John Stanley, Shifnal, Shropshire; Chas. Sturges, Sidney Square, Mile End; Richard Henry Thomas, Ibstock, Leicestershire.

FELLOWS elected at a meeting of the Council on the 13th inst.:—Messrs. Francis Bennett, Gateshead, diploma of membership, dated Feb. 3, 1832; Henry Bickersteth, Cape Town, South Africa, Jan. 5, 1838; Samuel William Brown, Lewisham, June 1, 1827; William Henry Brown, Lewisham, Aug. 26, 1836; Thomas Burlton, Leominster, Nov. 20, 1835; John Strange Chapman, Army, Dec. 9, 1825; Oscar Moore Passey Clayton, Percy Street, May 11, 1838; Thomas Coe, Bury St. Edmunds, July 4, 1838; John Crouch, Bruton, Somerset, Nov. 15, 1833; George Daglish, Wigan, Lancashire, April 20, 1827; John Dickenson, Wrexham, March 20, 1835; Benjamin Dulley, Wellingborough, Jan. 28, 1829; Charles Edwards, Cheltenham, Aug. 24, 1838; Edward Evans, Cardiff, March 21, 1834; Frederick Fry, Maidstone, July 2, 1830; Benjamin Hands, Hornsey, Middlesex, Sept. 3, 1819; Thomas Haslehurst, Claverley, Salop, Aug. 18, 1826; Henry Hayward, Aylesbury, May 8, 1835; Thomas Howitt, Lancaster, April 29, 1831; William Howitt, Preston, April 3, 1833; Mark Wilson Jackson, Stamford-Baron, May 26, 1826; William Jackson, Penrith, Dec. 2, 1814; Robert Jones, Long Melford, Dec. 1, 1820; Thomas Lewis, Gosport, Aug. 20, 1813; William Major, Camberwell, Oct. 4, 1833; Stephen Edward Piper, Darlington, June 22, 1838; Arnold Rogers, Hanover Square, April 16, 1830; Thomas Siddoley, Leigh, Lancashire, Dec. 15, 1820; Henry Lindsell Sopwith, Tonbridge Wells, April 28, 1835; George Southam, Salford, Manchester, July 20, 1838; Warrick Walter Wells, Bengal Army, May 8, 1835; and William H. Blewitt Winchester, Westbourne Terrace Road, Feb. 16, 1838.

LICENTIATES IN MIDWIFERY admitted at a meeting of the Board of Examiners in Midwifery on the 12th inst.:—Messrs. John Samuel Beale, Harrow Road, diploma of membership, dated Dec. 11, 1846; Theodore Duka, India, Oct. 7, 1853; James Hester, Oxford, Oct. 7, 1853; Benjamin Kerr, Cowes, Isle of Wight, Nov. 5, 1852; Robert Knaggs, Swindon, July 19, 1852; Henry Frederick Marley, Padstow, April 29, 1853; Thomas Peete, Cannon Street Road, July 17, 1851; George Whitefield Sparke, Finsbury, Oct. 7, 1853; Thomas Tomlinson, Maldon, July 11, 1853; and Thomas Wiglesworth, Coleford, June 18, 1852.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XLIV.

LONDON: FRIDAY EVENING, NOVEMBER 4, 1858.

NEW SERIES.

TO CORRESPONDENTS.

SPACE DEVOTED TO METEOROLOGY. We have to thank the numerous correspondents who have replied to our appeal on this point; and to intimate, that in consequence of the preponderance of opinion being decidedly opposed to the occupation weekly of more than one page of daily meteorological tables, we have resolved not to exceed that space in our new volume.

OZONE OBSERVATIONS. After the 1st January, these columns will be regularly filled.

MR. JEANS' REPORT. We are requested to state that the reason why the maximum is left blank in the 6th column, is that the observations are made in a town where the sun's rays are so interfered with in the winter by the surrounding houses, that they cannot be depended upon. For this reason, Mr. Jeans proposes to omit these observations from the end of September to the beginning of April.

ABERDEEN DEGREES. We cannot answer the letters which we are constantly receiving on this subject.

LETTERS FOR THE JOURNAL must invariably be accompanied by the name and address of the writer.

PRIVATE LETTERS, without a signature, are very objectionable; and we beg to say, that we never act upon information so supplied. If there are homeopaths and advertising quacks upon the roll of members, we shall be glad to assist in securing their expulsion; but we cannot make charges of the kind which have been forwarded to us by several anonymous correspondents within the last fortnight. We advise our correspondents to lay the facts before the Medico-Ethical Committee for their advice and aid. We can speak of ethical principles and laws; but it is not the Editor's province to enforce laws, or censure members by name, for their delinquencies.

THE LATE ACCIDENTS FROM CHLOROFORM.

IN another part of the present number, we have given the details of some deaths from chloroform, which have occurred since we previously made a report on the subject. Three of these deaths have taken place in this kingdom, within a short time of each other. Like nearly all the accidents from chloroform, they have happened just preparatory to, or during surgical operations. In the cases which occurred in University College Hospital, there was fatty degeneration of the right ventricle of the heart, which, however, was not known or suspected beforehand. The other patients were strong and tolerably sound in organisation. These accidents cast a gloom over the otherwise brilliant discovery of anæsthesia in surgery; and, although they are few in comparison with the thousands of instances in which the patient is saved from intense suffering with no ill effects whatever, yet they do not fail to cause a certain amount of apprehension, both in the patient who resolves to take chloroform, and the surgeon who has to administer it, or operate during its use. We fear that, unless the effects of chloroform become better understood, or unless

precautions be adopted which are not in general use at present, accidents will continue to happen now and then in surgical operations.

With the history of these accidents before us, it is right to draw attention to the circumstance that no case has been recorded in which death has been caused by the exhibition of chloroform in midwifery. It is our opinion that no such case has occurred; and this we consider to be due to the very moderate chloroformisation which suffices in obstetric practice, in comparison with what is required in surgical operations. The only case we have heard of in which even danger was incurred by the administration of chloroform in labour, was one in which all the most ordinary precautions were utterly disregarded. It happened in France, and is related in the *Bulletin Général de Thérapeutique* of August 15th. M. Boinet, the practitioner, having to apply the forceps, gave the handkerchief, on which about 3ij of chloroform had been poured, to the patient's husband, telling him to remove it when his wife became insensible; but the husband, being engrossed with the operation, left the handkerchief on his wife's face. She was reduced to a state of suspended animation, but was fortunately resuscitated by means of insufflation performed from mouth to mouth.

To conclude, nothing has occurred, either in our practice or reading, but what confirms the opinion we expressed in this Journal of May 27th, "that the cautious inhalation of the vapour of chloroform during labour is entirely free from danger, and calculated to afford merciful relief from pain in one of the most agonising trials of humanity."

THE CITY RECORDER'S OPINION ON ADVERTISING QUACK SCOUNDRELS.

THE City Recorder, like many other of our high and mighty ones, seems to have determined not to let the opportunity slip of bestowing a patronising wink on the charlatans who pollute the press with vile and indecent advertisements, or of showing that he considers the honourable members of the medical profession as one and the same with the impostors on whom he bestows his benevolent smiles.

In passing sentence on a person calling himself Hamilton (whose execrable bills have more than once been thrust into our hands in the streets of London), for an indecent assault on a young woman, the Recorder made the following remarks:

"It was a most gross and serious matter; for a woman, when she placed herself in the hands of a medical man under such circumstances, was in a manner defenceless. It was of the utmost importance that women, who were compelled to seek advice and expose the maladies under which they laboured, should not be in any way deterred from so doing by the fear that their position would be abused and taken advantage of. He should not deal harshly with him (Hamilton), because he was not a regular practitioner, nor because he was an advertising doctor, but for the reason stated."

Such is the language of the Recorder of the City of

London! They contain nice food for bitter laughter; but let us think of them seriously. A man, who lives by a nefarious practice, commits an occasional crime, which is very virtue compared with the iniquitous business hourly practised by him as a means of existence. For the occasional crime he is brought before the London judge. The judge has a fair opportunity of showing his abhorrence of *all* the prisoner's evil deeds, and, in some degree, of punishing them all; but, instead of doing so, he punishes the man for the most doubtful of his offences, and takes especial pains to be merciful to—we had almost said, to applaud those that are most heinous and perpetual.

What hope can there be for the reformation of the world from the grossest of sins, while these opinions stream from the bench of justice? They are the pabulum of quackery and imposture, however innocently delivered. They soothe the public feeling into quiet submission to what it knows to be wrong. They rouse the impudence of quackery to its utmost, and fill it with new life. When Dr. Hamilton escapes from his temporary retirement, the world may again find itself in the hands of the law-defended impostor. The delicate visual sense of Oxford Street may once more take in, and convey to the delicate mind, marvellous truths of "cures extraordinary", and glorious obscenities, that claim the brothel for a birth-place. There, too, the worthy Recorder, witnessing all this, may have great cause to rejoice that he drew in the reins of justice mercifully, and subjected to such gentle and brief punishment the man who pursues a calling so useful to the public, and so honourable to humanity.

HOMŒOPATHIC MEMBERS OF THE ASSOCIATION.

From information which has been communicated to us, we suspect that the names of two persons practising the homœopathic form of quackery are contained in the list of members published at p. 915 of our number for Oct. 21st. In these circumstances, we think it right to publish certain laws of the Association by which such persons can be got rid of.

The following laws were adopted at the anniversary meeting of the Association held at Oxford in 1852:—

"1. Candidates for admission to the Provincial Medical and Surgical Association, shall be required to state, in writing, to the members proposing them, that they neither are, nor intend to become, professors or practitioners of Homœopathy.

"2. When any member is convicted by the Central Council, or by any of the Local Councils, of publicly professing Homœopathy, of practising Homœopathy, or of holding professional intercourse with a Homœopathic professor or practitioner, this conviction, along with the necessary proofs of its justice, shall be officially reported by the Secretary of the Central Council, or by the Secretary of any of the Local Councils, to the next ensuing anniversary meeting of the Association; that it shall then be competent for the meeting, provided there be a concurring majority of two-thirds of those present, to direct the president in the chair to erase the name of such convicted member at once from the roll of members; but that it shall likewise be competent for the meeting, by a simple majority, either honourably to acquit the accused, or to accept from him, in entire satisfaction for his conduct, an expression of regret, and a promise not to repeat it; or to postpone final judgment till the next anniversary meeting."

NEWS AND TOPICS OF THE DAY.

ROYAL COLLEGE OF SURGEONS:—PASS LISTS. The following gentlemen were admitted members of the College at the meeting of the Court of Examiners on the 18th ult.:—Messrs. Thos. Prior Hall; John Wright, Mount Sorrell, Leicestershire; John Major Coleman, Wolverhampton; Wm. Williams Thomas, Fishguard, Pembrokeshire; Richard Eustace, Royal Navy; Joseph Packard, Yoxford, Suffolk; Thomas Duncan, Chelsea; Frederick Trestrail Bond, Hon. East India Company's Service, Bombay; and Thomas Joseph Cookson Powell, Bristol. At the same meeting of the Court, Mr. Charles Harper passed his examination for naval surgeon. This gentleman had previously been admitted a member of the College, his diploma bearing date July 2, 1849.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

BARRETT, Thomas, Esq., elected Surgeon to St. Catherine's Hospital, Bath.
BEGBIE, J. W., M.D., appointed Physician to the Cholera Hospital, Edinburgh.
BEVAN, Philip, M.D., appointed Professor of Descriptive Anatomy in the Royal College of Surgeons in Ireland, in the room of Dr. Hart, resigned.
DE MÉRIC, Victor, M.D., elected Surgeon to the German Hospital, Dalston.
MAXWELL, Dr., appointed Physician to the Worcester Dispensary.
SIMPSON, George, Esq., elected Resident Medical Officer of Queen Adelaide's General Dispensary, St. Luke's.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

*BATT, Edwin Augustine, Esq., Surgeon, at Witney, Oxfordshire, aged 52, on October 22.
KEMBALL, V. C., Esq., late of the H.E.I.C. Med. Service (Bombay Establishment), at his residence, 6, Chester Place, Hyde Park, aged 73, on October 20.
KRAMER, Professor, the eminent Aurist, last week.
THOMSON, Sir James, K.C.B., Physician General of the Bengal army, at Calcutta, on August 25. He was seized with a fit of apoplexy at a meeting of the Medical Board, at 11 A.M., and died at half-past 10 P.M.

ORIGINAL COMMUNICATIONS.

THE IATRO-METEOROLOGY OF
HIPPOCRATES.

By ALFRED HAVILAND, Esq.

It will be interesting to those engaged in making observations in that branch of medical science, which may with propriety be termed *iatro-meteorology*, to know that the great Hippocrates anticipated them in their appreciation of its value, as one of the helpmates of medicine. They will find in his writings, especially in his "Epidemics", "Aphorisms", and "Airs, Waters, and Places", very many minute meteorological observations in connexion with disease; and when we consider how deficient he was in those appliances, which modern science has given to us to facilitate our pursuits, we cannot but acknowledge the consummate wisdom and foresight of one, who saw the relation between atmospheric changes and disease more than two thousand years ago, and who was nearly, if not quite, as advanced in this department of medical knowledge as the learned of the present day.

Hippocrates says, in the opening paragraph of his treatise *Περὶ αἰέων, ὁδῶν, τόπων*, "Whoever desires properly to investigate the art of medicine, must do thus: First take into

consideration the seasons of the year, and how each is capable of operating (on the system); for they not only do not resemble each other, but differ widely from one the other in the changes (they bring about). Then the cold and hot winds (must be noted), especially those that are common to all nations, and then those that are peculiar to any particular district."*

His mode of observation, which will be found in the first and third books "*Περὶ ἐπιδημιῶν*", was very simple: in these instances he gave a description of the season of *three* different years, particularised the peculiarities of each season, and then concluded with an account of the most remarkable diseases that prevailed during each. The assemblage of the meteoric phenomena observed during the year, he comprised under the term *κατάστασις*, which is equivalent to "the state" or "constitution" of the seasons, for instance "*τῶν ὁρέων*."

We will proceed at once to a short detail of these observations, and for the sake of easy reference will place them in a tabular form.

* "*Ἱπποκρίτης δὲ οὕτως βούλεται ὁρᾶν ζητεῖν, τὰδε χρὴ ποιεῖν—πρῶτον μὲν ἐνθυμέσθαι τὰς ἑσας τοῦ ἔτους, ὅτι δύναται ἀπεργάζεσθαι ἐκάστη· οὐ γὰρ ὅμοια οὐδὲν, ἀλλὰ πολλὰ διαφέρουσιν αὐτὰς· τὰ ἐκαστῶν καὶ ἐν τῇσι μεταβολῇσιν· ἔπειτα δὲ τὰ πνεύματα τὰ θερμὰ καὶ τὰ ψυχρά· μάλιστα μὲν τὰ κοινὰ πᾶσι ἀνθρώποις, ἔπειτα δὲ καὶ τὰ ἐν ἐκάστῃ χώρῃ ἐπιχωρία ὄντα.*"

FIRST CONSTITUTION. (*Κατάστασις πρώτη*).—Observations made at Thasos. (Ἐν Θάσῳ.)

Season.	Rain.	Wind.	Temperature.	Cloud.	Snow, etc.	Name of Diseases.	Remarks, etc.
<i>Autumn.</i> (ἑθιμοκρατοῦ περι- σημερινῇ καὶ ὑπο- πληθῶν.) About the autumnalequi- nox and under the Pleiades.	A great deal of rain, which was constant and soft. ὁδῶν πολλὰ ζυνεκέ- μαλθακά.	Southerly. ἐν νοτίοις.				Cynanche paro- tidea. Inflammation and pain of the testicles. Dry coughs.	ἐπάρματα δὲ παρὰ τὰ ἄτα. φλεγμοναὶ μετ' ὀδύνης ἐς ὄρχιν.
<i>Winter.</i> Χειμῶν. τὸ ἔξολον ἐς γὰρ χειμῶνα ὁκοῖεν ἢ γίγνεται. The win- ter was on the whole very like spring.	Droughts. ἀέχμοι.	Southerly. Slight north winds. χειμῶν νότιος, σμηκρὰ πνεύματα βόρεια.				Hoarseness. Cynanche, etc.	πολλοὶσι δὲ βήχες ξηραὶ- βήσσουσι καὶ οὐδὲν ἀνάγουσι. φωναὶ βραγχώδεις.
<i>Spring.</i> ἦρ.	Slight rain. σμηκρὰ ὁσμῶν.	Spring south- erly. ἦρ νότιος.	Cool. ψυχρὸν.			Fevers.	καῖσοι. Moderate, however, and unat- tended by any hæ- morrhage. Never fatal.
<i>Summer.</i> Θέρος.	No rain. ἀνυδρία.	Etesian winds, rare, small, and irregular. Ἑττοῖαι, ὀλίγα, σμηκρὰ διεσπαρ- μένως ἐπνεύ- σαν.		Very cloudy. πολλὰ ἐπι- νεφέλων.		Phthisis (acute). Phthisis (chronic). Fevers.	Those who had a predisposit. to phthi- sis took to their bed. φθινώδεις κατα- κλιθῆσαν. (Remittent type of Munro?) πυρετοὶ πολλοὶ ξυνεχῆς.
<i>Autumn.</i>						Phthisis and fevers.	Phthisis fatal. The fevers were not so.

GENERAL REMARKS. He seems to hint that the fevers were dependent upon the droughts, etc., in the spring, which he intimates arose from a former opposite and northerly state of the weather, ἐκ τῆς πρόσθεν καταστάσεως ὑπεραντίης καὶ βορείου. Hippocrates also remarks that the cases of phthisis were the only fatal ones.

SECOND CONSTITUTION. (Κατάστασις θυνέρεα.)—Observations made at Thasos. (Ἐν Θάσῳ.)

Season.	Rain.	Wind.	Temperature.	Cloud.	Snow, etc.	Name of Disease.	Remarks, etc.
Autumn. Commencement. Πρὸς τοῦ φθινο- πάρου. During the Pleiades and until their setting.	Stormy and rainy. ὕγριοι καὶ προεπληγνύμενοι.	Strong north- erly and south- erly. ἐν βορείοις καὶ νοτίοις πολ- λοῖσιν.					
Winter. Χεῖμων.	Much rain and great torrents. ὕδατα πολλὰ, λαύρα, μεγάλαι.	Northerly. χειμῶν δε βόρειος.	Not unsea- sonably cold. οὐ λίην δε ἀκαίρως τὰ τῶν ψυχρόν.	Occasion- ally fair. μικαῖθρια τὰ πλείστα.	Snow. χιόνες.		
After the <i>Winter</i> <i>Solstice.</i> Μεθ' ἡλίου τροπῆς χειμερινῆς.	Much rain. ὕδατα ξυνεχίως πολλὰ.	Winterly storms and north, in- stead of Ζεφύρου (west). ὀπισθο- χέιμῶνες μεγά- λοι βορέαι πολλὰ.		Tempest- uous and cloudy. οὐρανὸς λαί- λαπῶδης καὶ ἐπινέφε- λος.	Snow. χιόν.		"The whole season having been generally wet, cold, and subject to a north wind, people were for the most part healthy during the winter, but early in the spring many required medical assistance." N.B. All the later meteoric phenomena continued until the equinox.
Spring. Ἑρ.	Rainy. ὕδατῶδες.	Northerly. βόρειον.	Cold. ἥρδὲ ψυχρόν.	Cloudy. ἐπινέφελον.		Ophthalmia (purulent?)	ὀφθαλμία ῥεώδης. This ophthalmia was painful, and the dis- charge unconcreted. It lasted in some in- stances until the au- tumn.
Summer. Θέρμς.		The Etesian winds blew constantly. Ἑτησίαι συνέ- χες ἐπνευσαν.	Not un- usually sultry. οὐ λίην καὶ ματῶδες.			Dysenteric affec- tions. Tenesmus. Lientery. Diarrhoea (bili- ous), with thin, copious, and un- digested dejec- tions.	Many of these affec- tions followed the fe- ver that prevailed, on which dropsy some- times supervened, and then a fatal result was generally the sequel.
Autumn. Περὶ ἀρκτούρου.	Much rain. πολλὰ καὶ ὕδατα.	Wind in the north. Ἐν βορείοις.				Watery stools. Strangury. Bilious vomiting. Fevers of various sorts. Convulsions. Small rashes. Swellings about the ears. Strangury. Abscesses. Sweatings.	<i>Semitertian.</i> There were many deaths from fevers. Those swellings did not suppurate, but were often determined to the joints. These supervening were considered crit- ical.

(a) Thasos, now Tasso, N. lat. 40° 30', E. long. 24° 28', is a small island in the north of the Grecian Archipelago (the Aegean Sea), on the coast of Thracia, now Roumelia, in the south of Turkey. It was remarkable for its fertility, insomuch that it became proverbial. Geologically considered, the island is composed of pure white marble, and has mines of gold and silver; and, with regard to its meteorological position, according to A. Petermann, it is situated about the isothermal line of 58° Fahr. average mean annual temperature. This author also encloses it within the region of south-west winds, and places it in a central position in relation to the northern and southern limits of the cultivation of the vine. Galen says of Thasos (vol. xvii, A., p. 36, ed. Kühn), "that this island, being situated just opposite the coast of Thrace, is exposed to cold northerly winds."

The first part of the third section of the *Aphorisms* of

Hippocrates is devoted to meteorology in its relation to disease; and the observations display the wonted sound judgment and acumen of this celebrated author. He says, in his *General Observations*,—

"That the changes of the seasons are especially concerned in the production of disease, and that the great alternations from heat to cold, and so forth, have also their due effect." (Aph. i.) "In well established (regular) seasons, if they bring forth their various products in proper time, the diseases are regular, and easily brought to a crisis; but, in changeable seasons, the diseases are variable, and determine with difficulty." (Aph. viii.) "In those seasons wherein there may occur on the same day both heat and cold, autumnal diseases may be expected." (Aph. iv.) "Every disease may occur at all times of the year, but some take place, and are more acute, at certain seasons." (Aph. xix.)

THIRD CONSTITUTION. (*Kardavasis* πρώτη).—Observations made at Thasos. (Ἐν Θάσῳ.)

Season.	Rain.	Wind.	Temperature.	Cloud.	Snow, etc.	Name of Disease.	Remarks, etc.
Autumn. Ἐπὶ ἀρκετοῖς ὡδαίνον, καὶ ἐν ἀρ- κετοῖς. About the equi- nox. ἐπὶ δὲ ὁση- ρῶν καὶ μέγχι πλε- ύθος.	Much rain. ὡδαίνον πολλά. Southerly rains. νότια βροχὴ ὡδαίνον.	Northerly. ἐν βορρῆσιν. Southerly? ἐν νότιῳ?					
Winter. Χεῖμα. Χεῖμα.	Droughts. ἀνίχμοι.	Winter northy. High winds. χ. βόρρειος. (πρὸς πύματα με- γάλα.)	Cold. ψύχρα.		Snow. χιόες.	Paraplegia. (Apoplexy.) Hæmorrhage. Disorders of bowels.	παρωληγία. It was fatal in some instances (καὶ τινες αὐ- τῶν ἐθνησκότων), espe- cially in elderly per- sons.
Spring. About the equi- nox. Ἐπὶ δὲ ὁση- ρῶν.	Slight rains. Droughts. βαρὺντα ὡδαίνον. ἀνίχμοι.	Northerly. Violent storms. ἐν βορρῆσιν καὶ μέγχι μεγίστα.	Cold. ψύχρα.			Ardent fevers. Difficult parturi- tion. Abortions. Eruption of measles during fevers.	Accompanied in fa- vourable cases by epi- staxis and other kinds of hæmorrhages. Fever subsequent to parturition (puerpe- ral?)
Summer. (α) Solstice. Ἐπὶ δὲ ἡλίου τροπῆς θερινῆς. (β) From Dog Days to Autumn. Μέτα δὲ κύνων μέχρις ἀρκτοῦρου.	Slight rain. ὡδαίνον ὡδαίνον. No rain, great and continued droughts. ὡδαίνον οὐκ ἔχον- τες, καθάρματα, κ.τ.λ. Southerly rains. νότια βροχὴ.	Etesian winds blew. ἐν βορρῆσιν καὶ μέγχι μεγίστα.	Great cold until dog days. με- γάλα ψύχρα. Summer. ἥλιος.			Dysentery. Ardent fevers and phrenitis. Hæmorrhage.	Epidemic during the summer. From which there were many deaths. These continued un- til the approach of winter.
Autumn. Ἐπὶ ἀρκετοῖς μέγχι ὁσηρῶν.						Swellings about the ears.	About the season of Arcturus many had a crisis on the eleventh day. Children be- came comatose.

Dry Seasons. "With regard to the constitutions of the year, on the whole, the dry are healthier than the wet, and less fatal." (Aph. xv.) The diseases, he remarks, of a dry season are "consumption, ophthalmias, pains in the joints, strangury, and dysentery." (Aph. xvi.) He further on observes, "that fevers are acute in droughts; and, if they prevail throughout the year, such will be its constitution, and such will be the diseases that we ought to expect." (Aph. vii.)

Wet Seasons. "The diseases that for the most part prevail in rainy seasons are lingering fevers, belly-flux, gangrene, epileptic and apoplectic attacks, and quinsies." (Aph. xvi.)

Winds. North. "As to the daily state of the weather, a northerly one braces up the body, makes it full of tone, active, and of a healthy hue, constricts the bowels, nips the eyes, and rather reproduces thoracic pains, if any have previously existed." (Aph. xvii.) "If the north wind prevail, coughs, affections of the throat, constipation, dysuria with rigors, pains in the sides and chest; and, when this wind prevails, we must expect such symptoms in the diseases that then occur." (Aph. v.)

South Wind. "A southerly (state of the atmosphere) relaxes and renders the body humid (perspiry), produces dulness of hearing, heaviness in the head, sluggishness of the movements of the eyes and the body generally, and relaxes the bowels" (Aph. xvii); also "dimness of sight, dulness (mental), inangur; and, when such winds prevail,

similar symptoms obtain in the diseases (that then occur)." (Aph. v.)

Temperament and Age. "With respect to the systems (of persons), some are either well or ill constituted for summer, whilst others are the same with regard to winter." (Aph. ii.) "Certain diseases and certain ages are either well or ill disposed for such and such seasons, places, or diet." (Aph. iii.) "As regards the seasons, children, and those who rank next them as to age, best enjoy, and are particularly healthy in, the spring and beginning of summer; old people (enjoy, etc.), the summer and a certain part of the autumn; and middle-aged persons, the remainder of the autumn and the winter."

Seasons. Spring. "The spring is most healthy, and least mortal." (Aph. ix.) In its relation to the age of persons, see above, under *Temperament and Age*. "The diseases of spring are the maniacal, melancholic, and epileptic, blood-fluxes, quinsies, coryza, hoarseness, coughs, leprosy, lichen, alphas, many kinds of ulcerating exanthemata, pustules, and arthritic diseases." (Aph. xx.) "If the winter have been southerly, rainy, and calm, and the spring dry and northerly, women, whose accouchments are expected in the spring, miscarry from slight causes; and if they be delivered at the full time, they bring forth weakly and diseased children, so that they either die at once, or live in an attenuated and diseased state. Among other mortals, there are dysenteries, dry diseases of the eyes, and, in elderly persons, catarrhs, that quickly carry them off." (Aph. xii.)

Summer. "Whenever the *summer* is like the *spring*, we ought to expect profuse perspirations in fevers." (Aph. vi.) "If the *winter* have been dry and northerly, and the spring rainy and southerly, of necessity there will be acute fevers, diseases of the eyes and dysentery in the *summer*, especially in the persons of women and men who are of a humid nature (sebaceous complexioned)." (Aph. xii.) "In summer, some of these diseases (referring to those mentioned under *Spring*), as well as continued fevers, ardent and tertian, much vomiting, diarrhoea, ophthalmus, gangrene (*σφρηδὸνες*) of the genitals, and sudamina (*ἱδρωσὶς* or *ἰδρωσάδια*)." (Aph. xxi.)

Autumn. "Autumn is obnoxious to consumptive persons." (Aph. x.) "In autumn, diseases are most acute, and altogether most fatal." (Aph. ix.) "If it (the autumn) be northerly and dry, it is favourable to persons whose systems are of a moist character, as well as to women; but, in other instances, there will be diseases of the eyes, unattended with discharge, acute fevers, chronic coryza, and, in some instances, hypochondriacism." (Aph. xiv.) "As to the diseases of autumn (among them there are many summer ones), there are also quartan and irregular fevers, affections of the spleen, dropsies, phthisis, strangury, lientery, dysentery, sciatic pains, quinsy, asthma, ileus, epilepsy, maniacal and hypochondriacal affections." (Aph. xx.)

Winter. "If the summer be dry and northerly, and the autumn wet and southerly, during the winter there will be headaches, coughs, hoarseness, coryza, and, in some instances, consumption." (Aph. xiv.) The diseases of winter, according to our author, are "pleurisy, peripneumonia, lethargy, coryza, hoarseness, pains in the chest, sides, and loins, headaches, vertigo, and apoplexy." (Aph. xxiii.)

I have thus attempted to give an outline of the views of Hippocrates on iatro-meteorology, by quoting verbatim the most remarkable passages in his works alluding to this most interesting subject; and shortly I hope to be able to compare these opinions with those prevalent before and after the period in which this great physician flourished. Many and valuable are the observations scattered through the ancient medical classics; and their perusal cannot fail to arouse in the minds of truly scientific men, not only a deep veneration for the ancestors of the medical profession, but a wholesome desire to emulate them in their patient and ever watchful study of the phenomena of disease.

Bridgewater, Oct. 25th, 1858.

ON THE USE OF NITRO-SULPHURIC ACID IN CHOLERA AND DIARRHŒA.

By W. J. ANDERSON, F.R.C.S., Accoucheur to the St. George's and St. James's Dispensary.

THAT oxygen is given off most rapidly from the blood in cholera, may be observed, even during life, by the speedy oxydation of the tissues, giving rise to that horrible emaciation so characteristic of the complaint; again, the cold and blue-coloured surface at a later period shows too plainly the large amount of oxygen which has been expended, and the fearful quantity of carbon which is now circulating in the slowly flowing blood. The patient has now a fluid passing through his blood-vessels, somewhat similar to that which exists in cyanosis, insufficiently stimulating to the nervous system, and consequently blunting the mental faculties (though not by any means obliterating them); and thence arises that strange and terrible apathy about their condition, which choleraic patients commonly exhibit.

Can a remedy then be found, which will readily yield up its oxygen and supply that element to the impure blood; and at the same time, by its astringent properties, tend to check the enormous exudation which takes place from the mucous surface of the intestinal canal? In our present state of knowledge, some of the mineral acids appear to be the best adapted to this purpose; and for certain reasons

about to be explained, a combination of nitric with sulphuric acid seems to me to be preferable to any other. The acid should be administered in tolerably full doses, and repeated at intervals, varying according to the nature and urgency of the case: for an adult we may give, acid sulphurici diluti f. 3 ij, acid nitrici diluti f. 3 j, in a six-ounce mixture, an ounce being the dose; but of course, in younger patients, this quantity must vary according to their age. We know that the blood contains an oxydised compound of iron, and that oxygen is readily taken up by compounds of the protoxide of iron from other oxydised compounds, while on the other hand compounds of the peroxide give up oxygen with the greatest facility. Hydrated peroxide of iron, in contact with organic matters destitute of sulphur, is converted into carbonate of the protoxide. The sulphur contained in the sulphuric acid will most probably restrain this action to a certain extent, and prevent such an excessive formation of carbonate of the protoxide of iron. Carbonate of the protoxide of iron, in contact with water and oxygen, gives off carbonic acid, absorbs oxygen, and is converted into the hydrated peroxide, which may again be changed into a compound of the protoxide.

	Atoms.	Equiv.	Per cent.
Iron - - -	1	28	77.8
Oxygen - - -	1	8	22.2
Protoxide of iron - -	1	36	100.0
Iron - - -	1	28	70
Oxygen - - -	1½	12	30
Peroxide of iron - -	1	40	100
Protoxide of iron - -	1	36	62
Carbonic acid - - -	1	22	38
Protocarbonate or carbonate of the protoxide of iron - - -	1	58	100
Carbon - - -	1	6	27.27
Oxygen - - -	2	16	72.73
Carbonic acid - - -	1	22	100.00

The large amount of oxygen contained in the nitro-sulphuric acid will then be called into play. It will enter into combination with the carbonate of the protoxide of iron, which will become decomposed, carbonic acid will be given off, oxygen will be absorbed, and the hydrated peroxide of iron will be the result.

	Atoms.	Equiv.	Per cent.
Nitrogen - - -	1	14	26
Oxygen - - -	5	40	74
Nitric acid - - -	1	54	100
Sulphur - - -	1	16	40
Oxygen - - -	3	24	60
Sulphuric acid - - -	1	40	100

We have then one atom of nitrogen and one atom of sulphur, combining with eight atoms of oxygen, to form nitro-sulphuric acid.

This plan of treatment, apparently so different from the saline system, is not in reality so much opposed to it as we might at first sight imagine. The same theory will here also hold good, as in both plans oxygen is the important agent which must be called into play to produce a beneficial effect. I do not believe that chlorine has any effect in this complaint; and I am therefore of opinion, that hydrochloric acid in the acid system (excepting as a mere astringent), and chloride of sodium in the saline, are both useless, as neither of them contain oxygen. In the saline treatment, oxygen is derived from other sources; and in the other case, is the important element.

			Atoms.		Equiv.		Per cent.
Potassium	-	-	1	40	83.34
Oxygen	-	-	1	8	16.66
Potassa	-	-	1	48	100.00
Sodium	-	-	1	24	75
Oxygen	-	-	1	8	25
Soda	-	-	1	32	100
Potassa	-	-	1	48	48.7
Chloric acid	-	-	1	76	61.3
Chlorate of potassa	-	-	1	124	110.0

Then, as chloric acid consists of one atom of chlorine and five atoms of oxygen, we must necessarily have six atoms of oxygen, combining with one atom of potassium and one atom of chlorine, to form chlorate of potassa.

			Atoms.		Equiv.		Per cent.
Carbon	-	-	4	24	35.8
Hydrogen	-	-	3	3	4.5
Oxygen	-	-	5	40	59.7
Citric acid	-	-	1	67	..	100.0
Carbon	-	-	4	24	47.06
Hydrogen	-	-	3	3	5.88
Oxygen	-	-	3	24	47.06
Acetic acid	-	-	1	51	100.00
Carbon	-	-	4	24	36.4
Hydrogen	-	-	2	2	8.0
Oxygen	-	-	5	40	60.6
Tartaric acid	-	-	1	66	100.0

The combination of any of these acids with potassa or soda forms a neutral salt, containing a large amount of oxygen, which doubtless acts upon the blood in a similar manner to that which has been explained; but these salts do not part with their oxygen as readily as the mineral acids, and are of no service in the premonitory diarrhoea.

This leads us to the "mechanical effect", as the astringent action of the nitro-sulphuric acid has been termed, and which differs merely in degree from that which is produced by the vegetable astringents. In all these latter substances, tannic acid is the active principle; and this being rich in oxygen, readily enters into combination with the various tissues, or more particularly with the albumen and fibrin contained in them—the same process taking place to a limited extent in the living body as occurs during the conversion of an animal's skin into leather. Albumen being an alkaline body, it is necessary that its alkali should be neutralised before any change of this nature can take place: the tannic acid then combines with the albumen as a base, and tannate of albumen is the result. It is, however, certain, that the oxygen plays an important part during this process; or why should this body (i.e., tannic acid, the very best adapted to its purpose) contain such a large proportion of this element?

Whether the theory here propounded be correct or not, it is quite certain that practice, both in this country and on the continent, has shown the utility of the mineral acids; and although, like all other remedies, they are unfortunately not infallible, nevertheless, they are about the best we can employ. In a large number of casual cases of diarrhoea, lately applying for relief, as well as many others which have occurred under my own treatment at the St. George's and St. James's Dispensary, this remedy has proved speedily effective with some very few exceptions; the diarrhoea and vomiting have ceased, and griping and cramps, when present, have been almost immediately removed. Emboldened by the success of this treatment in the adult, I have tried the same plan with children, and found it answer beyond my warmest expectation: it does not, however, act beneficially upon children at the breast; I suppose, on account of its decomposing the milk in the

stomach, and thus tending to keep up irritation; but, providing the child is not sucking, it matters not how young it is, the remedy has just the same effect as in the adult, relieving the griping, and stopping the purging and sickness.

16, Welbeck Street, Cavendish Square, Oct. 25th, 1853.

THE CONDITION OF THE FETAL HEAD AT THE FULL PERIOD OF GESTATION, AND ITS EFFECTS ON PARTURITION.

By GEORGE KING, Esq.

[Read at the Meeting of the Bath and Bristol Branch, September 29, 1853.]

THE state of the foetal head *in utero* may be considered rather an uninteresting and obscure subject for discussion; but it is one that may cause us much anxiety and trouble, as well as difficulty in practice. It is a subject, it seems to me, that has not been noticed, or has not attracted that attention among the professors in midwifery that it ought, and which I consider its importance deserves.

As there are various distortions and different dimensions of the female pelvis, so there may be, and often is, a great diversity as to the character and condition, as well as disposition in the size, of the foetal skull; and it is to this unusual development and altered state of the foetal cranium that I wish to direct the attention of the meeting, as I consider it to be a matter of much interest to us all. But to the obstetric practitioner it is of vital importance; and it has often appeared to me strange that it should have been so little noticed by authors and lecturers. It is this apparent neglect that has induced me to bring the subject before the members of the Association. I think that it is Smellie who says: "That difficult labours may proceed from circumstances belonging to the child that is to be born, from the extraordinary size of the body, or any part of it, from its being unable to facilitate the birth."

On trying a pain at the commencement of labour, if the membranes are ruptured we generally expect to find the foetal head presenting, giving the sensation of a smooth conical body, more cartilaginous or osseo-cartilaginous, and yielding, but not bony. It is also sometimes found to be hard, compact, firm, and highly ossified, and unyielding; and it is to this unusual state or texture, and want of uniformity in the cranium bones of the foetus, and its influence in connexion with parturition that I am anxious to draw attention. To the accoucheur, the condition of the foetal head at the commencement of labour is of the first importance, as it enables him to judge of the progress, and to form some idea as to the result of the labour.

In the cases to which I would now draw attention, the head will still be found within the cavity of the uterus, and the vertex generally presenting; and, from its hard and firm state, however strong the pains may be, its full rotundity would be retained, and the effect would be the expansion of the neck of the uterus, not the expulsion of the child. Such a head may also be found without the cavity of the uterus, resting on the brim of the pelvis; and if the action of the uterus has been frequent and strong, and suffered to go on until its expulsive powers are exhausted and the patient restless and irritable, we may expect to find on examination, some puffing or a pouch of the scalp presenting; but this long and continued uterine action we shall find has made no impression on the foetal cranium. Having made ourselves acquainted with the condition of the head, we ought never to allow such a waste of time and labour, and such annoying symptoms to be produced, while we have the means of preventing it by removing the cause. This ineffectual action of the uterus is the cause of those laborious and lingering labours which tend to that depression of the mental energy, and exhaustion of the physical powers of the patient, which often are so trying and annoying to the medical attendant, while the head of the child is endeavouring to adapt itself to the superior outlet of the

pelvis. This high degree of ossification of the cranial bones of the fetus, I believe, more frequently renders the operation of craniotomy and destruction of the child necessary, than does contraction or deformity of the pelvis; and with such a condition of the child's head, no natural uterine action, with all the auxiliary assisting muscular power of the abdominal muscles, could ever force it into the cavity of the pelvis, even if there were no contraction nor deformity; there would, therefore, be every moral certainty that the child could not be born alive, and that some assistance must be rendered to effect the delivery. To allow such an ineffectual sacrifice of the natural powers to continue without interference, would be risking the mother's life. In such a case, the forceps would be of no use, for it would be utterly impossible to compress such a head within their grasp, even if the head could be reached.

Turning, in cases of deformity of the pelvis, when it is considered impossible for the head to pass, has lately been recommended. This practice, I fear, would only be adding to the difficulty and render the case more complicated. If this mode of treatment is ever successful, it will be in consequence of the easy yielding and adaptability of the foetal head to the contracted outlet, and if the delivery could not be completed in this way, the opening of the foetal head above the brim of the pelvis, while the body is lying in the vaginal passage, would be, I believe, impossible, without doing some serious injury to the mother. With the vaginal passage thus blocked up, I have yet to learn how the hand and arm of the operator are to be introduced to the superior outlet of the pelvis to direct the perforating and bringing down the foetal head. And surely no man would have the hardihood to perform such an operation without such a guide and director.

The only remedy then, and, I believe, the only practice to be adopted is *embryotomy*; and, however revolting and painful to our feelings it may be to perform such an operation, it must be done, and quickly too, or the mother's life would be lost. In natural labours, passiveness and patience should be our motto; in preternatural ones, it should be promptness and performance. Most of the untoward circumstances and serious consequences that follow preternatural labours, arise from delaying, too long, what ought to have been done at once. In this condition of the child's head, it is very clear that craniotomy is our only resource; but it is not so easy a matter to perform this operation under the circumstances as some would imagine, for, instead of the foetal head being found fixed or resting on the brim of the pelvis, as is to be found in all illustrated representations of this operation, we should find it moveable, and the moment we touch it with a perforator it recedes, and we should have literally to bore through the *calvarium*, with no fixed or antagonistic power; and there would be no projections, chasms, or sutures to guide and direct us where to make the opening, but we should have to contend with the hard thick layers of bony deposit, which could only be controlled by an assistant keeping firm pressure above the umbilical region of the mother's abdomen. After making this opening, we shall require what Dr. Davies calls his osteotomist, a powerful and most useful instrument for breaking down cranial bones. In perforating the foetal head, we should endeavour to direct the point of the perforator to the base of the brain, in order to ensure the destruction of vitality. I have never heard the child cry *in utero*; but I have heard one make a most frightful noise after the head has been broken down and the brain smashed by the operation of craniotomy, while the body was still lying in the passage. Fortunately, the bedclothes drowned the sound, but it produced such a very peculiar sensation on the tympanum of my ears, and the gentleman that was with me, that neither of us will ever forget it.

When we have opened the head, some authors tell us that we should leave the natural pains to complete the labour. But this, in my opinion, would, in these cases, be bad practice. Having begun to interfere, we should complete the labour: to wait, would only be prolonging the patient's misery. For, after such highly ossified skulls are perforated,

it does not follow that they collapse or become lessened in size, like an hydrocephalic head, or one less firm in texture. Those who recommend such a practice must have forgotten that long distension, and an unusually high degree of tension, will have the effect of weakening the expulsive power of such a muscular organ, and is likely to produce an atonic condition of the uterus. This is well known by those who have often been called on to perform this trying and mutilating operation; for we have to break it down and bring it away by piecemeal. All writers on operative midwifery have given us ample directions and admonitions, for our guidance as to the dimensions of the outlet of the pelvis, and the size of the foetal head, but no allusion to its texture. I fear, were we to attend to all their advice, and directions as to measurement, it would involve a certain amount of delay, which would most certainly be incurring risk, as well as jeopardising the life of the mother. If ever a woman dies from the operation of embryotomy or craniotomy having been performed on the fetus in utero, it must be entirely in consequence of the effects produced on her constitution, from the head being impacted in the superior outlet of the pelvis, and by delaying the operation too long. If this operation be timely and properly performed, the practised accoucheur would never have any serious apprehensions for the safety of the mother, or his own reputation.

I believe it has been recommended by a professor of midwifery that we should wait for the death of the child before we make up our mind to operate; but this would be a painful and useless exercise of patience and forbearance. The stethoscope and auscultation are recommended, to enable us to ascertain the fact. This would be, in my opinion, awful practice, and trifling with the valuable life intrusted to our care. In cases of a high degree of ossification of the foetal head, and it is to this altered state of the head our energies must be all applied, we must pay no attention to the size of the pelvis, nor to the stethoscopic diagnosis. All our attention is to be directed to the condition of the head of the child; for here is an unusual large bony conformation of unyielding matter, incapable of adapting itself to the outlet of the pelvis: and all the natural uterine expulsive efforts of the mother to give birth to the child must be fruitless and impracticable; and those continued efforts of the mother to mould and adapt the child's head to the outlet may go on for hours, and even days, without causing death, or injury to the child. But the continued pressure and bumping on the soft parts of the brim of the pelvis would very soon produce inflammation and fatal consequences to the mother; therefore, to wait for the death of the child before we attempt to deliver, would be being accessory to the death of the mother; such practice, then, cannot be countenanced, and ought never to be adopted.

To enable us to be cognisable of auscultatory sounds, requires the greatest nicety of ear, and adroitness in examination, as well as patience in renewing the examination. But this is, certainly, not the time for the exercise of patience, nor practising the ear to sounds, or preparing us to become stethoscopists. All men do not possess delicacy of hearing, nor have they musical ears; they would, consequently, be as much puzzled by these stethoscopic observations as to the pulsatory sounds of the foetal heart, as they would be to decide what was harmony and what was discord in music. To adopt such a practice, except by practised auscultators, would be deceiving themselves and the patient.

The child, *in utero*, would retain the vital spark longer than the maternal constitution would hold out; while the long continued uterine expulsive efforts of the mother would have no serious effect on the child. The great secret is to know how and when to act: could we judge with certainty of the death of the child *in utero*, it would be, indeed, a happy circumstance.

The late Mr. Brookes, in his lectures to his pupils on operative surgery, used to tell them, when operating on the dead body, they were to fancy it a living subject. In this case, the reverse would be my advice. We are not, in these cases, merely to decide which would be the most appropriate mode, or what operation would be the safest for us to have

recourse to, in order to meet or overcome those protracted or difficult labours; but it is one of far higher importance and of much greater consideration. We have to muster all our moral courage to make up our minds to coolly and deliberately take away the life of a human being. This is a most trying and painful position to be placed in, and it is a cruel and deplorable case of professional expediency; but duty compels us, and we must act, as our vocation imposes on us this peculiar and distressing duty. Much has been written and said about the moral obligation and the responsibility of our situation in reference to this operation. I do not see why medical men should be suspected of want of feeling, or indifference, in those cases of duty and trial, when our skill and judgment are to be tested and called into action. I trust that none of us ever forget our moral or religious obligations, and that, on those occasions, we are only instruments in the hands of Him who is the giver as well as the preserver of life, in our responsibility to our patients; but must, more or less, be deeply impressed by the circumstances and the situation in which we are placed, as the medical attendant, having intrusted to our care and attention, by, perhaps, an affectionate and attached husband, a most beloved wife, and an endeared mother, whose children, though they may be unconscious of her situation and danger, are waiting for her recovery and anxiously expecting her return to her domestic duties. Surely, such a mother's life and such a family demand all our attention and sympathy. We are not only bound by our professional duty, but humanity would prompt us to aid and relieve such an endearing object; and such a life, surely, must be infinitely of more value than that of an unborn child. To save such a life must be all our anxiety and sole aim; this can only be done, when there is a large ossified cranium, by an early reduction of its size, and we have no other remedy. I am quite sure that no respectable accoucheur would rashly have recourse to such a fatal operation, unless driven to it by the strongest and most painful necessity; nor would it be justifiable in him until all hope shall have been extinguished of the competency of the natural powers to effect the delivery, and the condition of the cranial bones being fully and completely ascertained; the latter is of great importance, and this can only be known by the touch, or taking, and trying a pain as it is called. Although this mode of determining the state and situation of the parts is designated by the French *le toucher*, we have no term by which to express this but the one I have used, which is understood and familiar both to nurse and patient. The touch may be considered a very obscure sense compared to the sight; but it is the eye of the accoucheur, and it may, by use, be made to equal it. In operative midwifery it is our sheet anchor; and it is this index and a small hand that enable us to distinguish the state and condition of the presenting parts, and by the exercise of this sense we can only ascertain and judge of what is going on. When, on examination, we discover that there is a large head, and a high degree of ossification, we must also expect to find the uterus high up above the brim of the pelvis, and the neck distended over the whole head, like a thin membrane, presenting to the finger a hard smooth surface, which, on pressure being applied, recedes; the os uteri is also thin, and scarcely to be distinguished, and generally dilated about the size of a shilling, and there may be a slight discharge of liquor amnii; the membranes being so much distended, they may have given way, but the quantity of water that escapes would be very trifling, the head acting as a plug. This keeping back of the waters tends to keep the uterus in a buoyant state, and likewise supports the fœtus, and this, I consider, is the cause of the child being generally found alive; as the head of the child, in those cases, cannot, from its ossified condition, effect an entry into the pelvis. This natural instrument of dilatation, viz., the fœtal head, cannot exert its usual, and properly dilating powers upon the os uteri, however long we may defer or delay the operation. The obstetric practitioner has generally much faith, and calculates greatly on time and nature, and often relies on it to accomplish the delivery; but here time would be lost, and,

without manual assistance, nature would be soon exhausted.

Having ascertained the condition of the fœtal head, and being fully satisfied of the improbability and impossibility of its adapting itself to the outlet of the pelvis, by the natural efforts of the mother; we have no other resource but to reduce the size of the head. After duly investigating all the circumstances, and every point connected with it, we have only to determine on the operation; so that upon reflection, afterwards, we may feel quite free from compunction or self reproach. All that will be required is a certain amount of self command and moral courage, with a thorough knowledge of the vaginal passage, the pelvic cavity, and the situation of the uterus. A timid and nervous practitioner may be unnerved and terrified at the thought of the operation. Such a man should not attempt it; most certainly not by himself. I have operated frequently myself, with only the nurse and a female friend being present as a general rule. I should say that such an operation ought never to be performed alone, unless the operator had some practice, and had the entire confidence of the patient and her relatives; for, to be placed in a position to decide on the preservation or sacrifice of a life, without the benefit of advice or assistance, is a very serious and responsible situation to be in, and must test both our feelings, skill, and courage. I believe there is no operation that a surgeon is called on to perform which involves such serious effects and awful consequences as embryotomy. Our surgical operative abilities are generally called into action to preserve or to prolong life; but here our only solace is, that, if we do not destroy one life, both would be sacrificed: therefore, we can condole ourselves, and derive much comfort from the assurance, that the life sacrificed was unconscious, and no doubt void of feeling, perception, idea, pleasure, or pain.

Having, I fear, occupied too much time in describing the presentation of an unusually large ossified fœtal head, and its consequences, I will only spend a few moments in describing some of the circumstances in connexion with the operation of reducing the head. As I have said in a former part of this paper, the operation of craniotomy is, in a general way, a simple one; but in the case before us it is more complicated, and somewhat difficult; for here, instead of finding the head of the fœtus resting on the brim, or being impacted within the outlet of the pelvis, as the illustrated works on operative midwifery show us when describing this operation, we shall find it still within the uterus; and the perforating and breaking down of the head must be performed within the uterus itself, before we can get the neck of the uterus over it. The operation is hence rendered one of great nicety and care; for, when we have made an opening into the fœtal skull, we have not lessened its diameter; and when we introduce the craniotomy forceps within the uterus, we must take care that we do not mistake the hole we have made through the scalp for the lip of the os uteri, and include it within the teeth of the forceps; for we shall still find the neck of the uterus firmly attached to the head, and very thin; the scalp will also be found unusually thin.

In applying the forceps, one part or blade should be introduced into the opening made in the cranium by the perforator, and the finger directed to the other part; and, before the blade or teeth are brought together, if by the handle a slight push is given, the head will recede sufficiently to admit of their closing between the scalp and the neck of the uterus, without injury or entangling the parts; and enable us to break down the bones. Having done this, we shall have but very little difficulty in completing the delivery. Old writers tell us that, before we deliver, we must scoop out the brains; and, amongst the instruments necessary for the operation of craniotomy, recommended by Dr. Osmond, is a table spoon, which, I suppose, is to be used for this purpose. It is strange that any man, who must have had some practice, could ever suppose this process should be necessary, or that such a soft mass as the brain could interfere with the labour after the head had been

opened. I have never found this scooping to be necessary or advisable. Dr. Blundell tells us that we must convert the brain into a pulp, or, as he terms it, it must be pulped. I should say that the brains the Doctor met with were something like the cranial bones I am speaking about, rather harder than usual. After the head is broken down, I immediately proceed to bring away the mutilated body; and, I believe, the quicker this is done after the head has been opened, the greater the chance of the patient's recovery. There is nothing to be gained by delay. The blunt hook is the most useful instrument for this purpose. In performing this, I have often felt the want of an instrument with which I could hold fast a portion of the scalp, as well as pieces of bone, without cutting or breaking either; and with both included there would be less risk of lacerating the vagina with the sharp points, or spicula of bones; and also with such an holdfast we could greatly assist the uterine action. I have, therefore, had one made after my own fashion, which I call the operator's assistant.

The teeth of those I have seen are in the way, and are apt to get entangled in the membranes; and it is no easy task to disengage them when we wish to withdraw them. This is obviated in the instrument represented above, by having grooves in place of teeth. The hook handle gives greater freedom and liberty to the fingers and hand than the round one. Those who have had much to do with operative midwifery, and particularly craniotomy or embryotomy, must, I am sure, have felt the want of some such instrument. Much is to be done with the hands and fingers in those cases; but they become almost candled by the heat and moisture of the parts, and often, by the length of time employed, become almost useless, and we are obliged to delay the operation in consequence.

We must always bear in mind that the great object that we have in view in performing this operation is to save the patient much useless pain and misery, both of body and mind. And, in rendering this artificial assistance in labours, we must also not forget that nature is in an ordinary way rather slow in her movements, and we should endeavour to follow the ordinary and natural process in our movements, and not be in too much hurry; but, having begun, we

should never leave off until the delivery is completed. I have had, during my practice, to attend several times three women with contracted pelvis, with foetal heads not disposed to adapt themselves to the superior outlet: and two of these women had also been attended by other accoucheurs, who had also been obliged to destroy the children. These women, from not having had living children, generally require our services the oftener. This is to be regretted; but it is useless for us to moralise, or to remonstrate with them on the impropriety of their pursuing a course, the certain result and consequence of which must be a murderous operation upon an innocent child, and hazardous to their own lives. And this is not all. It will cause the surgical attendant much extra and anxious labour, as well as painful anxiety for the safety of the patient: and, with a perfect certainty of all these circumstances, and a foreknowledge of such painful and melancholy consequences, it seems to have no subduing influence over the passions of the *partes criminales*. Notwithstanding the general condition of the foetal head, and great deformity of the pelvis, each of the women has given birth to living and well formed children, at the full period of gestation. One of these patients I prevailed on to allow me to bring on labour between the seventh and eighth months, which I did successfully, and the child is now a fine little girl, near three years old; and in January last I confined the same woman with another living child, after a natural labour of about five hours' duration. She had had four children destroyed by the operation of craniotomy since her marriage. The other woman died after the birth of her fifth child. She was a powerful woman, and her labour pains were always very strong and frequent. I was not sent for till some hours after labour began. Knowing the sort of labours she had before, she thought the time had not come for my interference. On my arrival, I found the head presenting, the os uteri slightly dilated; and there had been a little discharge of liquor amnii. The uterus rested on the pelvic outlet. There was nothing to create alarm or anxiety; and, as was usually the case with her, she had plenty of energy and power. I left her, and promised to call again in three or four hours, which I did, when I was informed that her pains had left her for near two hours; and she complained of pains in her left side, just above the hip. I was surprised at her prostrate appearance, and gave 3ss tinct. opii in brandy and water. As the pains had left, and there was no advancement in the labour, I saw no chance of her being able to give birth to the child. I returned for my instruments, and reduced the size of the head, and delivered her. There was no hæmorrhage either before or after the delivery, and, in fact, nothing to account for the sudden suppression of the pains, and the other alarming symptoms. The removing the child did not improve her condition, although she bore the operation very well, and at first seemed to revive; but she did not rally, and died about fifteen hours after the delivery. A *post mortem* examination, the following day, explained the whole matter. We found a rent in the uterus, about two inches long, between the broad ligament and the neck, and externally to it there was a large clot of blood lying in the superior cavity of the pelvis. This rupture or giving way of the uterus was, I have no doubt, the consequence of the unyielding and ossified condition of the foetal head, and the very strong expulsive pains. She was seen before death by two of my medical friends, and I was assisted in the *post mortem* examination by Dr. Edwards, who was then residing in Bath. There was nothing remarkable in the appearance of either of these women; they were both what would be termed fine grown women. No visible sign of any deformity; and I should class their pelvis among the contracted, not the deformed. In both cases, the foetal head was at fault more than the pelvis.

Since I gave notice that I should bring the subject forward, I have attended a poor little emaciated deformed woman, with a remarkably contracted pelvic outlet, with her second child. With the first, embryotomy was performed. Her case had produced such a sensation in the

neighbourhood, that she had some difficulty in getting a surgeon to attend her. She had spoken to two, but both shrank from the responsibility. This I did not know until I was engaged; but, to their mortification and my surprise, I delivered her of a tolerable sized living child, at the full period of gestation. This, I believe, was entirely in consequence of its being a breech presentation and a yielding cranium. She was in strong labour about fourteen hours.

This ossified condition of the foetal head, I should state, is not of frequent occurrence; and it is very possible that a gentleman of a tolerable share of midwifery practice might have never met with such a case. I should say, from my own observation, that the average number would be about one in 500. In my own practice, I have had to perform the operation of craniotomy about fifteen times in upwards of 3,000 cases; but all of them were not in consequence of the ossified condition of the head of the child. Although these cases are rarely met with in practice, that is no reason why they should be entirely overlooked, and passed over unnoticed when they do occur in connexion with deformity of the pelvis and the operation of craniotomy.

I ought not to close this paper without stating that there may be small ossified foetal heads as well as large ones. As a proof of this, there are cases on record of children's heads having been fractured at the birth; the child having been expelled with the violent and rapid labour pains, while the woman was standing, or leaning on a chair, and the child dropping on the floor. Such an accident as this could never have occurred unless the cranial bones were highly ossified; an osseous cartilaginous cranium would never crack, even were the umbilical cord to give way.

This is a subject of interest and of immense importance in medical jurisprudence; and we, as medical men, when examined in cases of infanticide, should be able to explain and state that this state, condition, and texture of the foetal head, at the time of birth, is sometimes to be met with. It is well known that osseous matter may be deposited, and that ossification may go on within the cavity of the uterus; and the uterus itself has been found ossified. There is also a case recorded of an ossified foetus and uterus being found in a woman sixty years old. According to Professor Rokitsky of Vienna, it seems there is a larger proportion of osseous matter in breeding women than others. He says, "that a calcareous deposit has been almost constantly found in the internal surface of the skulls of women in the pregnant and puerperal state; and that the skulls become permanently thickened by frequent pregnancies." May not this superabundance of calcareous matter in the mother's system be conveyed to the foetus *in utero*, and be deposited in the skull, and be the cause of the remarkable degree of firmness I have noticed?

Bath, October 1853.

BIBLIOGRAPHICAL NOTICES.

EXPOSITORY LEXICON OF THE TERMS, ANCIENT AND MODERN, IN MEDICAL AND GENERAL SCIENCE; including a complete Medical and Medico-Legal Vocabulary. By R. G. MAYNE, M.D. Part I. pp. 152. London: 1853.

WE have very carefully examined the first part of Dr. MAYNE's Lexicon; and we have great pleasure in expressing our high and unqualified admiration of the manner in which it is executed. From the comprehensive character of the plan which the author has adopted, this Lexicon is suited to the requirements of every educated gentleman. It embraces "the correct pronunciation, derivation, definition, and application of the names, analogues, synonyms, and phrases (in English, Latin, Greek, French, and German,) connected with medicine, and employed in anatomy, astronomy, botany, chemistry, comparative anatomy, conchology, crystallography, entomology, geography, geology, geometry, ichthyology, materia medica, medical jurisprudence, microscopy, mineralogy, history, natural philosophy,

nosology, obstetrics, ornithology, pathology, pharmacy, physiology, surgery, trigonometry, and zoology."

We hope that the extraordinary industry and erudition displayed in this work may be rewarded by an extensive sale. While it is peculiarly adapted to the medical profession, it must prove equally useful to all scientific men, as well as to lawyers and coroners.

PRINCIPLES OF SURGERY. By JAMES MILLER, F.R.S.E.; Surgeon in Ordinary to the Queen for Scotland; and Professor of Surgery in the University of Edinburgh. Third edition: illustrated by 240 engravings on wood. 8vo. pp. 760. Edinburgh: 1853.

THIS new edition of Professor MILLER's classical work presents itself in an improved form. As its merits are generally known and deservedly appreciated, a critical examination is not required from us. We may say, however, that Mr. Miller's "Principles of Surgery" is a work of the highest class, and that, throughout its pages, the author shows himself to be equally sound and scientific in his medical treatment, and in his surgical practice. The constitutional character of local diseases is judiciously and practically treated; and the preeminence of conservative over destructive surgery is constantly maintained.

PERISCOPIC REVIEW.

MIDWIFERY AND DISEASES OF WOMEN.

RUPTURE OF THE UTERUS:—RECOVERY.

The following case is recorded by Dr. THOMAS CHRISTIE, of Lachate, Canada West, in the *Canada Medical Journal* for February 1853.

On the morning of the 21st August, 1852, he was summoned to attend Mrs. M. during her sixth accouchement. On arrival, he ascertained from the midwife that the patient had been in labour twenty-four hours; the pains had been regular, but not severe; the membranes had ruptured a few hours prior to his arrival; the head had advanced so far as to press on the perineum; just when she expected that another pain would have effected delivery, the patient felt something give way; since then the child's head had receded, so that it could not now be felt, and the pains were suspended.

Dr. Christie found the patient in bed, with her shoulders raised by an attendant; her face was pale and ghastly, with an expression of intense suffering and anxiety; the pulse was rapid and feeble, and the respiration difficult. The expulsive efforts had entirely ceased. Dr. Christie found a large rupture in the front of the uterus, through which the body of the child had escaped into the abdomen, the head still remaining in the uterus. Passing on his hand through the laceration, he succeeded, after a little search, in laying hold of one of the feet, and effected version and delivery without difficulty. The child was dead. After delivery, the patient was attacked with severe vomiting. A large dose of laudanum was administered. At the end of three hours, she appeared to be better. Dr. Christie then left her, prescribing thirty drops of laudanum three times a day.

August 22nd. She was much stronger, and had dozed almost constantly. He prescribed twenty drops of tincture of opium three times a day.

August 24th. He found her much worse. The pulse had taken on the inflammatory character; the tongue was coated; the abdomen extremely tender, and much distended. He bled her largely, and ordered eight grains of calomel and one of opium to be given three times a day, and a large blister to be applied to the abdomen.

August 25th. She was still worse; the pulse was 130; the tongue was brown and coated; the countenance anxious and pinched; she had hiccup and vomiting. Hot fomentations were applied to the abdomen, and calomel and opium were given every four hours.

August 26th. The calomel was omitted; the opium continued. She gradually made a perfect recovery.

FORENSIC MEDICINE.

EXPLANATION OF THE RARITY OF FRACTURE OF THE CRANIUM IN CHILDREN EXPELLED WHILST THE MOTHER IS IN THE ERECT POSITION.

Dr. J. G. SWAYNE, in commenting upon a case of fracture of the cranium in an infant at birth (*ASSOCIATION JOURNAL*, 14th October, p. 901), judiciously remarked, that the discrepancy in results between the experiments of Chaussier and the cases collected by Klein admits of a simple explanation. Chaussier allowed fifteen still-born children to fall from a height of eighteen inches on a paved floor; and in twelve of them, one or other parietal bone was fractured: whereas, in 183 cases collected by Dr. Klein, "in which the women were rapidly delivered whilst standing, sitting, or kneeling, not one child died, nor did any fracture of the bones or severe external injury take place." Upon these facts, Dr. Swayne remarked:—"When delivery takes place in a standing posture, the child falls obliquely instead of directly downwards, in consequence of its following the direction of the vaginal canal, which is obliquely downwards and forwards, especially near the os externum. It thus becomes expelled forwards against the clothes of the mother, and these, as well as the umbilical cord, serve to break the violence of its fall." These observations, in connexion with the facts recited, point out how necessary it is for the jurist in such cases to inquire into all the particulars of the birth; and they also show of how small importance the averment of delivery in the erect position may be of itself as a defence against a criminal charge of fractured cranium from violence to the fetus. The exact position of the mother, her dress, and the nature of the floor, must be determined and considered as essential elements in the cases. This is well illustrated by a communication lately brought before the Boston Society for Medical Improvement, by Dr. STORRER, published in the *American Journal of the Medical Sciences* for July 1853, p. 76. The child was expelled while the mother was standing leaning her head upon a shoulder of her nurse. The child's head struck with great force the floor, which fortunately was protected by a rug upon a carpet. The mother was of medium height, and the funis was thirty inches in length. Dr. Storrer alluded to the case (published some years ago) of a coloured woman suspected of destroying her child, it having been found with its cranium fractured. She insisted that the death of her child was occasioned by its having passed from her when she was walking upon frozen ground. Dr. Storrer thought that in the case which he had described, serious injury would have ensued had the head struck the unprotected floor.

SURGERY.

CONGENITAL ERECTILE TUMOUR OF THE TONGUE SUCCESSFULLY REMOVED BY LIGATURE.

J. G., aged 16, was admitted into the Royal Infirmary of Edinburgh upon the 1st of September 1852, on account of pain and increase of bulk in a congenital tumour of the tongue. After admission, she had a slight febrile attack, on account of which the operation was delayed till the 28th of September, when Mr. Syme, having passed a double ligature through the base of the tumour, separated the threads, and included the whole base of the tumour between two knots.—From *Monthly Journal of Medical Sciences*, Oct. 1853.

AMPUTATION OF THE PENIS FOR CANCER.

W. F., a pensioner, was admitted into the Royal Infirmary of Edinburgh on the 30th of August 1852. Two months before admission, he observed a pimple on the under surface of the prepuce, which continued to increase in size. His medical man applied first the nitrate of silver, then the sulphate of copper, without affording him any relief. The prepuce continued to increase in size, and in a short time he had complete phymosis: his medical man then slit up the prepuce, which gave him great relief for a time. The disease continuing to increase, red precipitate was applied; and after this, nitrate of silver was again tried; but neither of these applications had any effect in checking the disease. On admission, the tumour was firm, about the size of half an orange, involving the prepuce chiefly, and imbedding the glans in its centre. The surface was irregular, and discharged a thin foetid pus. The local pain was so intense as to prevent him from getting any sleep. As there was no glandular affection, Mr. Syme recommended the removal of the disease; and on the 8th of September, he removed the penis by a single sweep of a long amputating knife. About

twelve vessels required ligature. The patient felt himself at once relieved. In the words of the report in the *Monthly Journal of Medical Sciences*,—"He had no more pain; the wound healed quickly; and he had no difficulty in making water. Was dismissed from the hospital quite well on the 18th of September."

So far as it goes this case is interesting; but surgeons who report amputations of cancerous parts ought to endeavour to give an account of the patient for a longer period after the operation than ten days.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

THE HÆMOSPASTIC APPARATUS OF DR. JUNOD.

Dr. JUNOD, a physician formerly residing at Berne, has for many years given his attention to the possibility of producing a state of syncope, or, short of this, of arresting inflammation, without the loss consequent on the removal of blood. He has for this purpose contrived an exhausting apparatus, which is applied to a part distant from that affected, and thereby produces a diversion from the general circulation of a large amount of blood, which again becomes available for use after the removal of the apparatus. The following wood-cut represents the application of the instrument.

We have before us a report, signed by Dr. Scott, Deputy Inspector-General of Army Hospitals, and by Staff-Surgeons G. R. Dartnell and Dr. J. Forrest, of Chatham, as to the efficacy of Dr. Junod's apparatus. They say:

"Although most of the cases in which it was used were chronic, and not fairly suited to test the merit of the instrument as a therapeutic agent, we have been well satisfied with the general result, and feel convinced that it is calculated, when properly persevered in, and used with discretion and judgment, to aid powerfully the surgeon, as well as the physician materially, in the cure of diseases, especially those of an acute and inflammatory character, and attended with local congestion, such as cerebral affections, pneumonia, hepatitis, rheumatism, amaurosis, ophthalmia, etc."

They mention cases of obstinate intermittent neuralgic headache, pain and inflammation of the stump, and general febrile symptoms in a case of amputation of the fore-arm twenty-four hours after operation; also cases of iritis, of chronic conjunctivitis, etc., in which the use of the instrument produced relief.

"The apparatus is now being tried in a case of amaurosis of nearly two years' standing, after an attack of fever, in a young soldier of the 15th hussars. On admission to the general hospital, this patient was suffering from continued headache, tenderness of the scalp, flushed face, etc., the pupils widely dilated and quite immovable; now, after fifteen applications of the instrument, the headache, scalp tenderness, and flushed face, are entirely removed, and the iris of each eye has become ordinarily sensitive to the stimulus of light, the pupils contracting to their natural dimensions. No improvement of vision, however, is yet apparent."

Dr. Junod believes the application of his instrument to be an efficacious means of removing the internal congestions and the consecutive symptoms in cholera.

The apparatus to which we have referred is certainly ingeni-

ous, and we believe it well worthy of a trial in cases where it is an object at once to relieve congestion of some important organ, and to economize the amount of blood.*

TOXICOLOGY.

DEATHS FROM CHLOROFORM.

Since we last reported a fatal case of inhalation of chloroform in the *JOURNAL* of April 1st, four deaths have been recorded from this cause. In the *Gazette des Hôpitaux*, of June 16th, a case is reported by M. de VALLET, surgeon-in-chief to the Hôtel Dieu d'Orleans. The occurrence took place on the 20th of last December, but was not previously published.

The patient was a soldier, aged 27; he seemed of strong constitution, and had no affection contra-indicating the use of chloroform, which was administered with the intention of removing two encysted tumours; one on the left cheek, and the other behind the right commissure of the lips. A gramme of chloroform, *i. e.*, about fifteen minims, were poured into a conical sponge, which was gradually approached to the face. In a minute, no effect having been produced, four grammes, or about a drachm more, was added, and, a short period of agitation having occurred, the patient became insensible in about four minutes. At this moment, the respiration was natural. The state of the pulse was not ascertained. The first incision on the tumour near the mouth had scarcely been made, when the patient became suddenly pale, and the respiration ceased. Amongst the means used for reviving the patient were, tracheotomy, and artificial respiration with an elastic tube. A current of galvanism was also passed through the region of the heart, by means of needles; but these measures were of no avail.

On an examination of the body, the vessels of the brain were found to be empty. The heart was very flaccid, but not diseased. There were some soft coagula in the right cavities; the left cavities were empty. The lungs, as also the liver, spleen, and kidneys, were much congested with blood.

The *Monthly Journal of Medical Science*, for November, contains the account of a fatal case of inhalation of chloroform, which occurred in the Royal Infirmary of Edinburgh, on September 28th.

A tobaccoconic, aged 43, of intemperate habits, had been three months in the infirmary, under the care of Dr. DUNSMURE, for stricture of the urethra. The operation of dividing the stricture, in the method practised by Mr. Syme, was determined on, and the chloroform was administered by Dr. Struthers, a gentleman who had long been in the habit of applying it. Dr. Dunsmure says: "While the patient was inhaling the drug, he struggled considerably, and became a good deal congested in the face and head. He seemed to take a slight convulsion, like an epileptic fit, and such as I have seen on several occasions in people who have led an intemperate life. During the convulsion, the handkerchief containing the chloroform was removed to some distance from the face. In a short time, the inhalation took effect, and he began to snore, and although still violent, the chloroform was removed from the face entirely, and the handkerchief placed under the pillow. As soon as the patient became more quiet, he was pulled down on the table, and placed in the proper position for the operation. I then shaved the perineum, and was just going to make my first incision, when one of the assistants said that his pulse was becoming weak. The posterior tibial, Mr. Spence remarked, was good, but, in a second or two afterwards, both gentlemen exclaimed that the pulse was gone". The breathing did not cease before the pulse. At the moment when the pulse and respiration had ceased, "the face was much congested, the jaws were firmly closed, and the pupils were dilated". Dr. Dunsmure forced open the mouth and pulled out the tongue with forceps. Artificial respiration was had recourse to, and in a few moments the patient made a long inspiration. This was followed by a second, by a third at a longer interval, by a fourth at a still longer period, and then a fifth, when all attempts at natural breathing ceased. No pulse could be felt after it first stopped. Tracheotomy was performed, in order that artificial respiration might be carried on more effectually. The external jugular was opened, and about two ounces of blood flowed. Galvanism was applied, with the effect of causing the diaphragm to descend as during life, but all these efforts were in vain, the diaphragm gradually lost its contractility, and, at the end of an hour, the case was given up as hopeless.

An examination of the body was made by Dr. Gairdner, and all the organs were found to be in a pretty healthy condition. The pericardium contained about half an ounce of serum. Both sides of the heart contained blood, the right side more than the left. Blood more than usually fluid. Muscular tissue of heart generally flabby, and rather pale, but not distinctly disorganised to the naked eye. Microscopic examination shewed the fibres of the heart to be nearly normal, though scarcely so distinctly striated as in some cases. The lungs were somewhat congested.

The quantity of chloroform used in this case was about an ounce.

A death from chloroform occurred in University College Hospital, on October 5th, to a man aged 40, on whom Mr. QUAIN was just about to operate for strangulated hernia. It is reported in the *Medical Times* of October 22. Chloroform was administered on a piece of lint, which was held at first three or four inches from the face, and then brought to within an inch and a half. One fluid drachm was first put on the lint, and, at the end of three or four minutes, forty minims more were added. For three or four minutes the pulse and breathing remained natural, and nothing unusual presented itself. Within a minute after the second quantity of chloroform was added, the patient struggled violently. During these struggles, Mr. Hillier, the resident medical officer, who administered the chloroform, was unable to feel the pulse, on account of the constant motion of the patient. The struggling lasted about a minute; and, on its ceasing, the patient commenced to breathe with a loud rough stertor. The lint was at once removed from the face, and Mr. Hillier felt for the pulse, but could not find any. Cold water was dashed on the face. Two or three short inspirations took place, with the kind of stertor just mentioned; then two or three long inspirations, and the breathing ceased. Artificial respiration was immediately resorted to, and, within a minute, galvanism was applied to the back of the neck and the diaphragm. Under the influence of these agencies, the patient gasped about three times at intervals, but after this no signs of life were exhibited.

Autopsy was made by Dr. Garrod, thirteen hours after death. Rigor mortis was well marked in all the limbs. The blood was very fluid in all parts of the body.

The abdomen was tympanitic, pressing the diaphragm upwards. The pericardium contained about an oz. of colourless fluid. The heart was quite collapsed and empty, which may have been due to the fluidity of the blood. Its anterior aspect was covered with fat, almost hiding the muscular substance. Weight of heart 7½ ounces; valves healthy. The walls of the right ventricle were flabby and pale. At some parts the muscular substance was very thin, being much encroached on by fat. In several places, especially near the apex, there was scarcely any muscular fibre visible. Much fatty degeneration of the muscular fibres of this ventricle was discovered by the microscope. The left ventricle was pale, flabby, and very friable. Both lungs were crepitant throughout; not much engorged. Brain not congested. Liver, kidneys, and spleen normal.

The remaining fatal case of inhalation of chloroform occurred on Oct. 20th, in St. Bartholomew's Hospital, in a patient under the care of Mr. PAGET, who intended to apply the actual cautery to a sore in the vagina, of a canceroid nature. The subject of this case was a stout, florid, young woman, aged 22, "formerly of dissolute habits; but apparently, with the exception of the local ailment, in perfect health. She had been in the hospital several months, and, about a fortnight previously, had been put under the full and prolonged influence of chloroform for a like purpose, without the occurrence of any untoward symptoms whatever." The chloroform was given with an inhaler—a padded, metal cup, fitting over the nose and mouth, containing a sponge, and supplied with valves. A drachm by measure was first poured on the sponge; but, as the administration did not immediately commence, a considerable part of this was, no doubt, wasted. After a short inhalation, a second drachm was supplied, and subsequently, the further quantity of half a drachm. "The patient had gone through the usual stages of excitement, etc., and the last dose was scarcely used as she sank off, almost immediately after its application, into a state of complete insensibility, unattended by any alarming symptoms. About five minutes had been occupied in the inhalation, and probably not more than a drachm and a half of the fluid really inhaled. The apparatus was now removed from the face; and the patient having been drawn into the proper position, Mr. Paget was about to commence the operation, when Dr. Black, who throughout had kept his finger on the pulse, noticed it to have become extremely feeble and fluttering. Almost immediately afterwards, the patient's countenance was observed to be dusky, turgid, and con-

* Dr. Junod is at present residing at 36, Cardington Street, Hampstead Road, London; and will with pleasure give information with regard to his apparatus to any member of the Association who may feel an interest in the subject.

gested, and the respiratory movements began to be performed at long intervals, and by slight, catching efforts." Cold water was dashed on the thighs, face, and breast, and the failure of the respiration becoming shortly complete, Mr. Paget began artificial respiration, by alternately blowing into the nostrils, and compressing the chest. Various other measures were used, amongst which were galvanism, but without any good result; and after three quarters of an hour, they were laid aside as hopeless. "It was noticed, that immediately after the first alarming symptoms, the pupils were of medium size—neither contracted nor dilated. All efforts at respiration ceased about two minutes after the first indications of failure; the pulse, however, as a very feeble flutter, was felt occasionally for, at least, two minutes later."

Autopsy performed by Mr. Paget, twenty-two hours after death. The countenance was still bloated and suffused; the *post mortem* rigidity was moderate in degree. The corpse was very fat. "The thorax was first examined, and nothing whatever abnormal could be detected in any of the viscera; the lungs were healthy, and crepitant in every part; their posterior lobes were not more congested than is seen in almost every examination; the heart was collapsed, but not contracted, and containing a small quantity of fluid blood in each cavity, was of normal size and proportions in every respect, and its muscular structure, examined by the microscope, shewed no degeneration." "The brain, its sinuses, ventricles, etc., were all carefully examined, and neither in texture nor quantity of blood was anything abnormal detected." The blood, in every part inspected, was quite fluid, and without the slightest trace of coagulum. An ounce or two of it being collected, and allowed to stand in an open vessel, it did not coagulate, nor change much from its dark purple colour.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

SATURDAY, OCTOBER 22ND, 1853.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.

PRESERVATIVE POWER OF METALS IN CHOLERA.

BY DR. V. BURQ.

Dr. ROUTH communicated the paper for Dr. Burq. The author related a case of cholera, which occurred in the Hôpital Cochin, in which the external application of a copper band arrested the cramps; on the removal of the copper plates the cramps re-occurred. He found subsequently, on inquiry, that workers in copper and brass were remarkably exempt from cholera. This was the result of a careful and personal investigation in nearly all the metallic workshops in Paris, in which from 100 to 600 (and over) workmen were employed. In all these the mortality never exceeded 5 in 1000, and in many it was *nil*; and this in the midst of a neighbourhood in which the population was decimated. In many cases the wives suffered, while the workmen escaped. Dr. Burq investigated the matter in other countries—Sweden, Vienna, Russia, Turkey, and England. In all the same exemption was observed. In many cases also, it was remarked that removal to a copper mine, or even district, arrested choleraic symptoms. The exemption of Birmingham, Sheffield, etc., he explained in this manner. The individual cases so tested amounted, in round numbers, to about 300,000. A review of all these facts led him to conclude: I. That nearly all metals with strong electric affinities were in different degrees preservative; but of all these, copper and steel were most so, the mortality being almost null among workmen engaged in working these two metals. II. With a view of resisting cholera, he recommended the presence of copper and steel ornaments in rooms, as also plates worn next the skin on the body. III. In the treatment of cholera, their internal administration, especially copper, in powder in the metallic state, as also application externally of plates. These plates he calls armatures; these he prefers to the salts of metals. The memoir concluded with an attempt to explain these phenomena, which he did not believe depended on any electric or galvanic influences; indeed, these he considered rather noxious than otherwise. He suggested—1, that, as in the production of ozone by phosphorus, an atmosphere affected by copper might be so modified that the cholera poison could not exist in it; 2, it might be due to minute absorption of oxide of copper by the skin and lungs, acting in a similar manner upon the system.

CANCER OF THE UTERUS, PROBABLY INDUCED BY INOCULATION.

BY B. W. RICHARDSON, ESQ.

Mr. RICHARDSON related the case of a woman, aged 57, who was under his care, suffering from cancer of the uterus. Her husband died in January, 1848. For three years before death, he had had pain in and a strong discharge from the generative organs; and a year before his death, cancer of the penis manifested itself. They had connexion frequently until within sixteen months of his death. The woman first consulted Mr. Richardson in October 1851. She had been complaining for some time of general debility, with a discharge from the vagina and a "bearing down" sensation. On examination, he found a large cancerous mass occupying the vagina; and the walls of the cavity were covered with a number of excrescences. The first symptoms had appeared about two years and nine months after the death of the husband: and Mr. Richardson thought it an interesting subject of inquiry, whether the woman had been infected by her husband.

ON PERICARDITIS. BY F. SIBSON, M.D., F.R.S.

After alluding to the difficulty of distinguishing between bellows-sound, as indicative of endocardial, and friction-sound as indicative of exocardial disease, and referring to the opinions of various authors on the subject, Dr. Sibson observed that it was evident that other tests, besides the difference of the two murmurs, are required to distinguish between pericarditis and endocarditis in the early stages, when the discrimination of the disease is so important. The principal test proposed by Dr. Sibson is the employment of pressure. If a friction-sound exists, that sound invariably becomes louder and harsher by making moderate pressure with the end of the stethoscope, so as to bring the surfaces closer together. In the earliest stage, pressure will often excite a friction-sound when none was previously present. In a case of pericarditis under Dr. Sibson's care in St. Mary's Hospital, pressure brought out a sound like a bellows-murmur. A few leeches were applied. Next day there was a loud to and fro *frottement*. In the advanced stages, when the effusion of fluid, by separating the two surfaces, extinguishes the sound, pressure, by bringing the surfaces again in contact, will restore the lost friction-sound. An interesting illustration of the effect of pressure in exciting sound presented itself in a patient of Dr. Sibson's in St. Mary's Hospital. A female affected with phthisis had ascites. On displacing the fluid, and pressing on the liver, a to and fro thrill was felt under the finger; as was anticipated, a loud, harsh, double, creaking noise, during inspiration and expiration, was heard on making pressure with the end of the stethoscope. On withdrawing the pressure, the sound ceased. After death, the surface of the liver was found to be roughened.

The first patient in whom Dr. Sibson observed the effect of pressure in reinforcing *frottement*, was a female affected with pericarditis, in the Nottingham Hospital, on 25th November, 1838. Since that period, he has recognised this important sign in every case of pericarditis he has examined. He gave an account of it in his paper on the "Position of the Internal Organs", in the *Provincial Medical Transactions* for 1844. This effect of pressure is rarely excitable in men after the age of forty-five, the cartilages being then firm and unyielding. The only point to guard against is the possibility of exciting anæmic murmur in very young persons.

The anatomical position of the *frottement* ought to be noted. Dr. Stokes found friction-sound to be audible generally only over the region of the heart, while endocardial murmurs are transmitted beyond that region. This rule holds good in the early stages, and while effusion is present; but when the fluid disappears, and the surfaces come in close contact, the noise may sometimes be heard extensively over the front of the chest. To the right of the lower sternum, over the right auricle, the friction-sound is usually double, soft, and equally loud, during systole and diastole; to the left of the sternum, over the right ventricle, it is also double, but harsher, especially during systole; over the apex it is generally only systolic. The form of the region of pericardial dulness is important, being conical, the point upwards reaching to the top of the sternum. When the effusion is great, the heart is often raised, so that the impulse is felt, and the *frottement* and heart in the second and third spaces instead of the fifth. Dr. Latham observes, that at this stage not only is the impulse raised, but the thrill felt by the hand is raised also. Dr. Walsh has noticed the tilting upwards, during effusion, of the impulse of the apex from the fifth to the fourth intercostal space. Adhesions usually begin to form over the outer edge of the right and left ventricles. If so, the *frottement* ceases there, while it remains

over the base; the region of *frottement* with the advancing adhesion gradually narrows to the middle of the sternum, and at length, when adhesions are complete, the friction-sound suddenly becomes inaudible. If adhesions do not take place, the friction-sound may remain long after the pericarditis has ceased. If a patient is seen at this stage for the first time, care must be taken not to treat him as if he were subject to the disease in the acute stage. In pericarditis, especially if it affects the central tendon of the diaphragm, the respiratory movement of the upper ribs is excessive, especially on the right side, while that of the abdomen is restrained.

With regard to treatment, there can be little doubt that the severe antiphlogistic plan pursued by Bouilland, and to a lesser degree by Dr. Taylor and others, has increased rather than diminished the mortality, besides inducing a tedious convalescence in those who recovered. A few leeches to the region of pain, opium in repeated doses, on Dr. Graves' plan, with, in severe cases especially, small doses of calomel, in addition to the treatment previously pursued for the acute rheumatism, will usually prove adequate to meet the disease. Dr. Risdon Bennett had proved, that in many cases the treatment need not be altered when pericarditis sets in in acute rheumatism. The great object is to restrain the disease, without doing damage to the constitution, so that the convalescence may be as rapid and complete as possible. Indeed, each case must be treated on its own merits. After the acute stage, food, stimulants, and tonics, properly apportioned, are in many cases well borne, and they materially shorten the convalescence. It is not by one sign only, however distinctive, that pericarditis is to be ascertained, but by the combination of the various diagnostic signs, not neglecting either the character, nearness, or rhythm of the friction-sounds, their limitation to the region of the heart, or extension beyond it, their reinforcement or actual production by pressure, the form and extent of the pericardial dulness, the presence of fluid, the seat of the impulse, the prominence of the cardiac region, and the altered movements of respiration, as well as the pain on pressure over the heart and epigastrium, the dyspnoea, and the various general symptoms, the sum of which go to inform us, more even than the physical signs, of the severity of the case, and to suggest the required treatment.

A discussion followed, in which Drs. Semple, Risdon Bennett, Sibson, Hare, and Theophilus Thompson, took part.

SATURDAY, OCTOBER 29TH, 1858.

FORBES WINSLOW, M.D., D.C.L., President, in the Chair.

CYSTORRHOEA PRODUCED BY A VASCULAR GROWTH AT THE EXTERNAL ORIFICE OF THE URETHRA. BY WILLIAM COULSON, ESQ.

Mr. COULSON related the case of a lady, aged 40, who had suffered for two years from a burning pain at the orifice of the urethra, constant desire to pass urine, with almost continual escape of that fluid in drops. She had lately been obliged to rise every half hour in the night, and a strong ammoniacal odour exhaled from her person. The urine was of a dark brown colour, strongly ammoniacal, containing much tenacious viscid mucus, and deposited considerable fragments of friable phosphates. The tenderness of the inflamed vulva, from the constant dripping of urine, was so intense, that walking was exceedingly painful, and any attempt at sexual intercourse produced great agony.

The orifice of the urethra was found surrounded by vascular and excessively sensitive growths. Dr. Golding Bird, under whose care the patient was, considering that the vascular growth at the orifice of the urethra was the exciting cause of all her symptoms, requested Mr. Coulson to see the patient. Mr. Coulson ascertained that no calculus existed; he applied the potassa fusa to the part, and, after four applications, the vascular tumour nearly, but not quite, disappeared; this treatment occupied about three weeks. The effect was remarkable: the urine became acid and clearer, the mucus rapidly decreased, and the phosphatic deposits disappeared; the patient was not called upon to rise more than once in the night, and could bear exercise with comfort. At this period, a sudden attack of menorrhagia occurred, which prevented the destruction of the growth from being completed. In a short time, the vascular excrescence returned, and all her old urinary symptoms appeared. Mr. Coulson then removed these growths completely, with a pair of scissors, and afterwards applied nitric acid freely to the bleeding surface. The result of this operation was most successful. The urine soon recovered its healthy character, she could retain it a considerable time, and had perfect control over the bladder. Her general health, which had been much impaired, was completely restored. Soon after this, she became pregnant, and miscarried at two months; she has, since this time (now at the end

of six months), remained in perfect health. Dr. Golding Bird had pointed out these growths as a cause of cystorrhoea. The rationale is at once found in the obstruction offered by the growths to the complete evacuation of the bladder. Some ounces of urine are always retained, and, becoming ammoniacal and foetid, act as an irritant on the mucous membrane, producing excessive secretion of ropy mucus and all the symptoms of calculus. Hence, in these cases, as in those lately described by the same physician, of prolapsus of the bladder into the vagina, causing the anterior wall of the canal to project between the labia, the cause of these painful symptoms is, retention of a portion of the urine and its decomposition in the bladder.

ON THE TREATMENT OF LABOUR, MARKED BY DEFECTIVE UTERINE ACTION, AND ON THE COMPARATIVE VALUE OF ERGOT OF RYE AND GALVANISM IN OBSTETRIC PRACTICE. BY ROBERT BARNES, M.D.

The author stated that in the range of obstetric practice there occurred a large class of cases characterised by defective uterine action. Two questions immediately arose: 1. What are the conditions of uterine inaction which call for interference? 2. What are the agents to be selected for the purpose of evoking the dormant energy of the organ? The first question was necessarily passed over, in order to direct special attention to the second. He adverted, however, so far to the first question, as to point out the extreme difficulty of determining in many cases the cause of the existing inertia, and the consequent danger of misapplying the agents in use for inducing contraction. He then explained the peculiarities of the action of ergot, insisting upon its dangerous properties. He enumerated the bad effects it might produce upon the mother; as rupture of the uterus and perineum; laceration and consequent mischief of the os and cervix uteri; prolapsus of the uterus and bladder; the depressing effect upon the pulse, etc. Then the injurious effects upon the child, and the frequency of still-born children in ergot labours were considered. He related an interesting case, in which he had had the opportunity of observing the effect of continued contraction in arresting the fetal circulation. The author doubted whether the restrictions upon the use of ergot, commonly recognised, were sufficient; he urged the necessity of no longer employing an agent so uncertain, so uncontrollable, and so dangerous; the more especially as we possessed in galvanism a safe and efficient power, adapted to every case in which ergot was considered to be necessary. The author then adverted to the various isolated writings upon the use of galvanism in obstetrics. He enlarged upon the advantages attending its use for the induction of premature labour, citing two original cases in illustration. He then considered its application in inertia uteri accompanying the first and second stages of labour. Then its use in the third stage, in retention of the placenta, and in hæmorrhage, citing cases of its successful employment. He next pointed out a variety of other cases in which galvanism might be most usefully resorted to; in paralysis of the bladder following delivery; in arrested uterine action from chloroformisation; in the excitation of respiration in still born children; in the expulsion of uterine polypi; in the evacuation of the uterus in case of hydatigenous placenta. The author then described the mode which he preferred in the administration of galvanism. He observed that it was certainly inconvenient and seldom necessary to adopt the usual practice of applying one pole of the battery to the spine and one to the cervix uteri. The application of the discs one on either side of the uterus was sufficient. He observed that galvanism did not act by primary excitation of the spinal centre, but by direct stimulation of the muscular fibre. This effect was thoroughly obtained by passing the shocks through the uterus, by applying the poles one on either side of the abdomen, and no obvious advantage was gained by passing the shocks through the uterus by the spine. The electro-magnetic apparatus constructed on the principles in ordinary use for medical purposes, was the best suited for obstetric use. He explained that the efficacy of this form of apparatus was owing to the production of a rapid succession of shocks. The author concluded his paper by enumerating some of the principal advantages of galvanism as an agent for producing uterine contraction, adverting to the extensive range of cases admitting of its employment; its perfectly manageable character and easy graduation and intermission: its certainty and efficiency; its safety; the possibility of employing it successfully in cases of exhaustion where no other remedy could be used; and the fact that it did not preclude the resort to other means.

EDITOR'S LETTER BOX.

CLIMATE OF MADEIRA.

LETTER FROM T. H. BURGESS, M.D., TO THE EDITOR.

SIR,—In a late number of the ASSOCIATION JOURNAL, Dr. George Lund, of Madeira, has undertaken to controvert some general remarks on the climate of Madeira, which I had occasion to make in my recent work on the "Climate of Italy".

Free discussion is always desirable on disputed subjects, especially those relating to so conjectural a science as medicine. It is the only sure method of arriving at the truth. But, in order to be useful, such discussion should be fair as well as free, and not open to the charge of misrepresentation.

Dr. Lund says: "Dr. Burgess, a recent author on the climate of Italy, declares change of climate in disease to be a delusion." I never wrote or thought anything of the kind; but I did write the following sentences, which Dr. Lund has not quoted: "In pointing out the inutility of the Italian climate for consumptive invalids, I should be sorry to be understood as denying the sanative effects of climate in all diseases. In several affections of a painful and distressing kind, the benefit to be derived from a well selected and appropriate change of climate is incalculable." (p. 8.) Dr. Lund complains that I have not given the whole of long sentences in my quotations from works on Madeira, in a general summary of those foreign climates most frequented; and yet his very next quotation from my work is as choice a specimen of interpolation as I have ever met with. It consists of seven lines; the three first of which are taken from page 1, the fourth line from page 3, and the remainder of the sentence from the middle of page 2, of my work.

This is the so called quotation: "There is no greater popular delusion than the belief in the existence of some undefinable specific virtue in the climate of Italy for pulmonary consumption. (page 1.) This foreign climate delusion is not confined to the rich invalid" (page 3); "he adds: "It is only when the disease is confirmed, and softening exists, that, in the great majority of instances, the patient seeks in a foreign climate that relief or cure which he believes nature has denied him in his own." (page 2.) So that Dr. Lund makes one "add" to a sentence in page 3 one which precedes it in page 2!

Dr. Lund says, correctly enough, that, "having no personal knowledge of the island, I have formed my opinions from the works of White and Dr. Mason, and the statements of Drs. Heintzen and Gourlay." But, that I have omitted to mention Mr. Murray's "Guide Book" because it was in favour of the climate, I altogether deny. No writer could speak in more glowing terms of the climate of Madeira than Mr. White, whose work I placed foremost in my necessarily short sketch of the climate of that island. Corinne herself could scarcely surpass him. Strangely enough, the eminent authority whom Dr. Lund cites in opposition to my statements is liable to the same charge of "want of personal knowledge of the island"; for Sir James Clark acknowledges his obligation to Drs. Heintzen and Renton while collecting materials for his article on Madeira. Indeed, if the merits of the deservedly popular work on the "Sanative Influence of Climate" were to be limited to those parts in which the distinguished author writes from "personal experience" of the climate, a considerable, and not the least deserving, portion of the work might be omitted. Well, Dr. Lund, who is a practitioner at Madeira, and has "personal knowledge of the island", will surely be able to enlighten, with original observations made on the spot, his medical brethren not so favourably situated. Can the reader believe that, in his long and laboured defence of the climate of Madeira, Dr. Lund does not give a single original idea, fact, or observation; that he is obliged to draw upon other writers for all his statements, and to prop up his defence by extracting Dr. Renton's tables from Sir James Clark's work? So far, then, as his "personal knowledge of the island" goes, he might as well have written on the climate of Kamschatka. One might suppose that a practitioner, so deeply interested in preserving the fame of the climate of Madeira, would have something else to offer than a mere *rechauffé* of stale and familiar observations, the fruits of others' industry.

Dr. Lund says, in reference to the variations of the atmosphere, that, out of 824 observations in this climate (he does not say by whom), we find only nine strong winds, and one presumed gale. Did the reader ever before hear of such a nondescript as a "presumed gale"? What does it mean? It is of a piece with another phrase equally unique, in which Dr. Lund talks of "enabling the system to throw the tubercular materials out of

the blood." Dr. Lund is very angry with Dr. Mason, who has written the best work on the climate of Madeira that has yet been published, because he takes an unfavourable view of the climate in relation to phthisis; and endeavours, to the best of his ability, to disparage the work, and throw discredit upon its statements. For example, he has again recourse to misrepresentation, when he says, "Dr. Burgess informs us that the instruments used were improperly placed: a fact which alone vitiates the whole of the results." From this, it would appear that I stated from my own knowledge that the instruments were badly placed; whereas I merely found the assertion in the volume of Dr. Lund's non-medical friend, Mr. White, who is an ardent supporter of the climate in a sanitary point of view; and, on the principle of hearing both sides, I gave the statement on Mr. White's authority. Of the truth of the assertion I had no means of judging. Dr. Mason and Dr. Gourlay both agree as to the frequency of consumption amongst the natives of Madeira; but Dr. Lund enters a caveat against the opinion of Dr. Mason, "because he did not speak the language!" Dr. Lund winds up his letter with the following strange jumble:—"Dr. Burgess thus sums up: 'Madeira, with all its sanitary fame, is no exception to this rule; [that is, it affords no proof of salubrity] as the meteorological observations of Drs. Heintzen, Gourlay, and Mason, incontestably establish.'" "Setting all other considerations aside," says Dr. Lund, commenting on this extract, "we [I] do not think that these three observers bear out this assertion in their own cases. Dr. Gourlay was not consumptive. Dr. Heintzen was originally sent out as a dying case, lived nine years on the island, and ultimately died from accidental exposure to the night air in an open boat. Dr. Mason, notwithstanding his neglect of means for preserving health, and devoting himself instead most assiduously to meteorological observations, lived in Madeira two years." What have "their own cases" to do with the meteorological observations referred to? Does it strengthen, or invalidate, or in any way affect them, to know whether those gentlemen had consumption or not? Where are we to look for positive information respecting the salubrity of this island, but from the local practitioners? Yet it is strange that so earnest an advocate as Dr. George Lund could produce nothing of his own to support his views. I am sure he will profit by the following remarks of the gifted editor of Dr. Mason's work on the "Climate of Madeira":

"It is singular that, in an island so celebrated for its salubrity, no regular meteorological records should be kept, or, at least, published; and that such difference of opinion should exist as to certain features in the climate. Dr. Mason most justly remarks, that the memory of the 'eldest inhabitant' is little to be depended on, if not supported by written and recorded observations; and it strikes me that the medical practitioners resident in the island can hardly allow the subject to be longer neglected, in the present advanced stage of science, without subjecting themselves to the reproach of indifference relative to the charge sometimes urged against them, of withholding the truth, under a dread that the *far famed climate of the island will not bear the test of close and accurate examination.*"

Since the publication of the article on the "Climate of Madeira", of which Dr. Lund so grievously complains, I have been favoured with several communications from persons who had resided in the island, fully confirming all that I had stated. I have had besides painful experience of the effects of a temporary sojourn at Funchal on several consumptive invalids, two of whom were hurried to the grave by their visit to Madeira. The particulars of these cases I shall publish in extenso in a new edition of my very obnoxious work. Meanwhile, I have only to state, that Dr. Lund has entirely failed to subvert any of the objections to the climate of Madeira urged by Dr. Mason, namely, "dampness, rains, injurious effects of the Leste (Atlantic blast), and heavy precipitation of dew."

Luxuriant vegetation may be very effective to gradually the senses, or to garish graves; but it is no proof of the salubrity of any climate. Neither is "balmy air", subject to vicissitudes, in a foreign climate, a whit more likely to arrest the progress of tubercular consumption in a native of England, than the strict Devonshire, Hastings, Cove or Undercliffe, however it may please invalids or practitioners to foster a "good delusion". Madeira is no exception to the rule; and of Dr. Lund's assertion

* "The strangers' burying-ground," says Dr. Lund, "has a fine appearance, and one Burgess, not a native, was seen to be in the habit of flowers, while reading with sadness the epitaphs on the graves of the young and joy of youth, having sought these flowers in the bosom of the earth through the influence of its being the only place where the flowers of friendship and love, and the flowers of the heart, are not buried."

wish to see the rival climate of Malaga (the latest novelty) attract all the wandering consumptive invalids thither, he will, by devoting himself "most assiduously to meteorological observations", endeavour to make out a better case than his last essay, in favour of the sanative fame of the "Island of the Blessed." (*Herodotus*.) I am, etc.,

T. H. BURGESS.

Half Moon Street, Piccadilly, Oct. 10th, 1853.

[In reperusing Dr. Lund's article, we find that the author's desire is to give an impartial view of his subject. His opinions are supported by Mr. Dyster's paper in last number.—EDITOR.]

DR. DAVEY'S REMARKS ON DR. SWAYNE'S CASE.

LETTER FROM J. G. DAVEY, M.D., TO THE EDITOR.

SIR,—Will you allow me to correct the observations attributed to me in the report of the Bath and Bristol Branch, at p. 894 of the *ASSOCIATION JOURNAL* for October 14th? Instead of saying that the "convulsions", in the instructive case read by Dr. Swayne, were dependent, *primarily*, on the injury done to the brain, I said that they *were*, it would appear, so reputed; but that I could regard them only as a mere sequence to the injury, i. e., as the immediate effect of the succeeding inflammation of the parts affected, involving, as such a pathological condition did, more or less effusion, thickening of structure, and such like; and that these so interfered with the normal relationship of the cerebro-spinal system and its bony parietes, or, in other words, so altered the relation of the containing and contained parts, that the spinal functions were necessarily interrupted, and *convulsions*, THEREFORE, were induced.

My object was merely to draw the attention of the members to the fact, that, inasmuch as the brain has really nothing to do with the normal motive powers else than *indirectly*, it can in no way be *directly* or "*primarily*" concerned in *convulsive movements*: such I do consider to depend on "*spinal irritation*" (I am represented as having expressed the very opposite opinion), but not to arise "*because the relation between the brain and spinal chord has been disturbed*", to quote the words attributed to me in the *Journal*. These involve so much mystery, and are altogether so incomprehensible, that I am desirous not to be held responsible for the same.

I am, etc.,

JAS. GEO. DAVEY, M.D.

Northwoods, Bristol, Oct. 19th, 1853.

MR. WINCHESTER'S METHOD OF TREATING FRACTURES.

LETTER FROM W. H. WINCHESTER, ESQ., TO THE EDITOR.

SIR,—From your editorial remarks in the *JOURNAL* of 21st October, on the "Prevalent Treatment of Disease", particularly of fractures, I am induced to think that an account of my method of treating these cases, with a description of the apparatus, may not be unacceptable to your readers, especially as it was designed whilst practising in the country, and for the very purpose of obviating the difficulties of which you speak.

In seeking for an efficient apparatus, my chief aim was to imitate nature; and, as perfect uniformity, a symmetry between the two halves of the body, is nature's invariable law, so I conceived, if by any means I could contrive an apparatus which should assume the form of nature, or, in other words, be capable of being moulded to a sound or healthy part for the use of an injured or diseased one, such mechanical appliance would not only be rendered as perfect as it is possible, and be generally useful, but afford the surgeon a fixed principle of action, and an unerring guide in the treatment.

After considerable thought, and taking all the requirements of the surgeon into consideration, I contrived the apparatus, of which I send you an engraving; its superiority over every other splint consists in its simplicity, universal applicability, and efficiency. One and the same splint doing the work of three or four. Whilst every other apparatus tends, more or less, to alter the original form of a limb,—whether made of metal, wood, gutta serena, or starch,—the direct tendency of this one is to preserve it, having, before its application, assumed the natural form. It consists of jointed pieces of wood, metal, or other suitable material, which have the power of being fixed at any desired angle; and in its application, is first laid against and fixed to the shape of the sound side, and then immediately turned and applied to the broken one, affording a complete support to the entire shaft of the bone, preventing retraction, and consequently

doing away with the ordinary means of extension, which are painful to the patient. To the country surgeon, a great saving of time will be effected in its use, as no unnecessary journey may be taken, but armed with this *multum in parvo*, he may sally forth and give immediate relief to his patient.

I am, etc.,

W. H. WINCHESTER.

14, Westbourne Terrace Road, October 27th, 1853.

Fig. 1.

Fig. 2.

Fig. 1 shows the splint. a. a. Pieces of wood, metal, etc. b. Joints, which are fixed at any angle. c. A crutch for the axilla, if necessary; and d. The foot-piece, both of which can be regulated to any length or angle. e. Studs for the straps.

Fig. 2 shows the splint applied to the broken side, after being adjusted to the opposite uninjured one. It will be perceived that even should both thigh and leg be broken, the same adjustment does, showing a great superiority over all other splints. It can be lengthened or shortened at pleasure, and a piece removed from any part, should there be a wound, without deranging the adjustment. f. Ball-and-socket joint for hip. g. Hinge-joint for knee.

Fig. 3.

Fig. 3 shows the straps used in the application of the splint. The size of the sound limb is taken when the splint is adjusted by means of the buckle with the lacing fastened. When applied to the injured limb the original size is still maintained by the buckle; and should swelling occur the lacing is loosened, allowing the strap to expand by means of a piece of vulcanized India-rubber inserted. As the swelling subsides the strap goes back to its original size, and is again laced. By this means the necessity for loosening the strap is avoided.

MEDICAL METEOROLOGY.

LETTER FROM GEORGE F. BURDER, M.D., TO THE EDITOR.

SIR,—At the present time, when the attention of the medical profession is so generally directed to the subject of meteorology in its relation to the public health, it becomes very important that investigations in this branch of science should be conducted upon sound principles, lest valuable time be wasted upon fruitless researches, and the progress of knowledge retarded by the hasty adoption of erroneous conclusions.

The following remarks have been suggested by the meteorological table published in your Journal of the 7th inst., taken in connexion with a circular reprinted from a previous number.

In reference to the table alluded to, it is not my object to point out errors either of plan or of execution in its strictly meteorological part, although here exception might be taken to more than one instance of apparent inaccuracy—as, for example, to the fact that the weekly mean of the barometric readings at 9 A.M. at two stations, Bedford and Uckfield, reduced to the level of the sea, differ about three-tenths of an inch; similar comparisons of observations taken at Clifton with those published by Mr. Glaisher rarely, if ever, giving a difference of as many hundredths.

My present object, however, is chiefly to point out what appears to me an objectionable principle in the medical department of the table; and I am the rather induced to do so, as this point is insisted upon in the circular as the distinguishing feature of the system. I allude to the very precise specification which is demanded of the *hour* of the commencement of a disease, or of the occurrence of death. I am aware that it is an invidious task to complain, or seem to complain, of excessive accuracy in the registration of scientific facts; nevertheless, it is certain that much time may be lost, and much laborious investigation misdirected, by the endeavour to secure a degree of accuracy in one element of a calculation totally inconsistent with the accuracy attainable in the other elements. If I might be permitted to state concisely my objections to this feature of the proposed system, I would say, first, that it is not likely to facilitate the discovery of truth; and secondly, that it will be very apt to lead to positively erroneous deductions.

That no laws can be safely deduced from such facts as are proposed to be supplied will, I imagine, be evident from a consideration of a special instance. Thus, on a certain day, we find it stated, that puerperal convulsions occurred at 11 A.M. Now, apart from the *prima facie* improbability of the supposition that the occurrence of these convulsions was determined either by the barometric pressure at that hour, the temperature or humidity of the air, the direction of the wind, the character of the clouds, the quantity of ozone, or the amount of rain fallen in the previous twenty-four hours,—apart from this, let us inquire what means we have of determining the condition of the various atmospheric elements at this particular hour? Clearly none. Let it be granted that the instruments are good, and that careful observations are taken twice a day—a frequency (to judge by the vacancies in the published table) greater than many professional men will find it convenient to maintain. On this supposition, the *weekly* mean of each element, after being subjected to the proper corrections, may be considered a close approximation to the truth. The *daily* means, though not to be relied upon for accuracy, may be regarded as a useful indication of the character of each day. Beyond this, we have positively nothing to go upon; for it must be apparent that observations taken at 9 A.M. and 3 P.M. scarcely afford even a clue to the determination of the special peculiarities presumed to exist at 11 A.M. To secure the result intended, hourly observations should be taken—an arrangement obviously impracticable.

It if be urged, that the precision complained of, however unnecessary, can at all events lead to no error, an answer is supplied to our hand by the circular already referred to. "If, however, when the wind is east, a case of toothache, neuralgia, diarrhoea (with or without cramps and vomiting), convulsions, epilepsy, apoplexy, menorrhagia, epistaxis, hæmoptysis, or premature uterine action, should occur, the barometer readings decrease either immediately, or in a few hours afterwards." "He also observes, that apoplexy, epilepsy, and sudden deaths, invariably occur with a prevalence of hail and snow showers." Can comment be necessary upon such statements as these? "Very interesting conclusions" they may be; but can we regard them as *reliable* conclusions, or, indeed, as anything but an illustration of the statement just now advanced? disproportionate accuracy of detail proving not only a useless refinement, but becoming likewise a snare to the investigator, in proportion as it is considered an equivalent for extended observation.

There are other points in the circular to which exception might justly be taken—as, for example, the specimen table of the relative prevalence of diseases under different atmospheric conditions; which table I have tried in vain to understand.

But it is unnecessary to add more. In writing what I have written, I have been actuated simply by a regard for the interests of meteorological science—interests which I conceive to be endangered by the adoption of what appeared to me to be an ill digested scheme.

It is truly enough remarked, that the Registrar-General's weekly tables are not sufficient for our purpose. They apply only to London; they take no account of non-fatal diseases; they do not even accurately represent the mortality of the week to which they profess to apply. We want observations from all parts of the country, returned with promptitude to some central station for publication and diffusion, including both diseases and deaths. These conditions are to some extent fulfilled by the scheme already commenced in your Journal. I would suggest, however, that, instead of stress being laid upon the day, still less upon the precise hour of the occurrence of a disease or a death, the observer should content himself, for the most part, with noting the weekly totals of each disease, and of deaths from each cause; experience showing that a week is the shortest period for which the atmospheric conditions can be accurately determined from observations taken once or twice daily. By some such plan as this, if it could be generally adopted and faithfully carried out, there can be no doubt that valuable results might be obtained.
